Programmazione concorrente

Laurea Magistrale in Ingegneria Informatica
Università Tor Vergata
Docente: Romolo Marotta

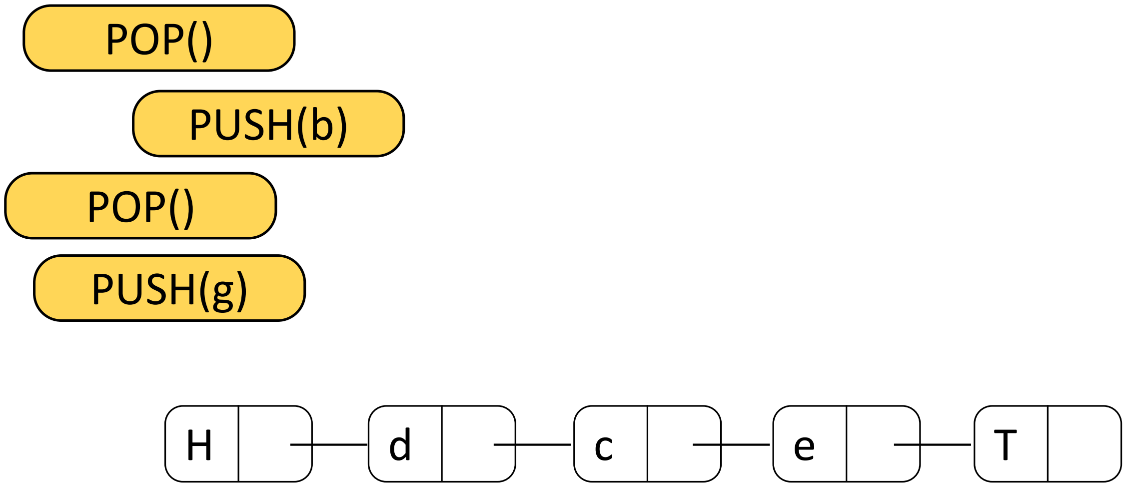
Concurrent data structures

1. Stack
2. Set
3. Priority queues
4. FIFO queues

Concurrent Data Structures: **Stacks**

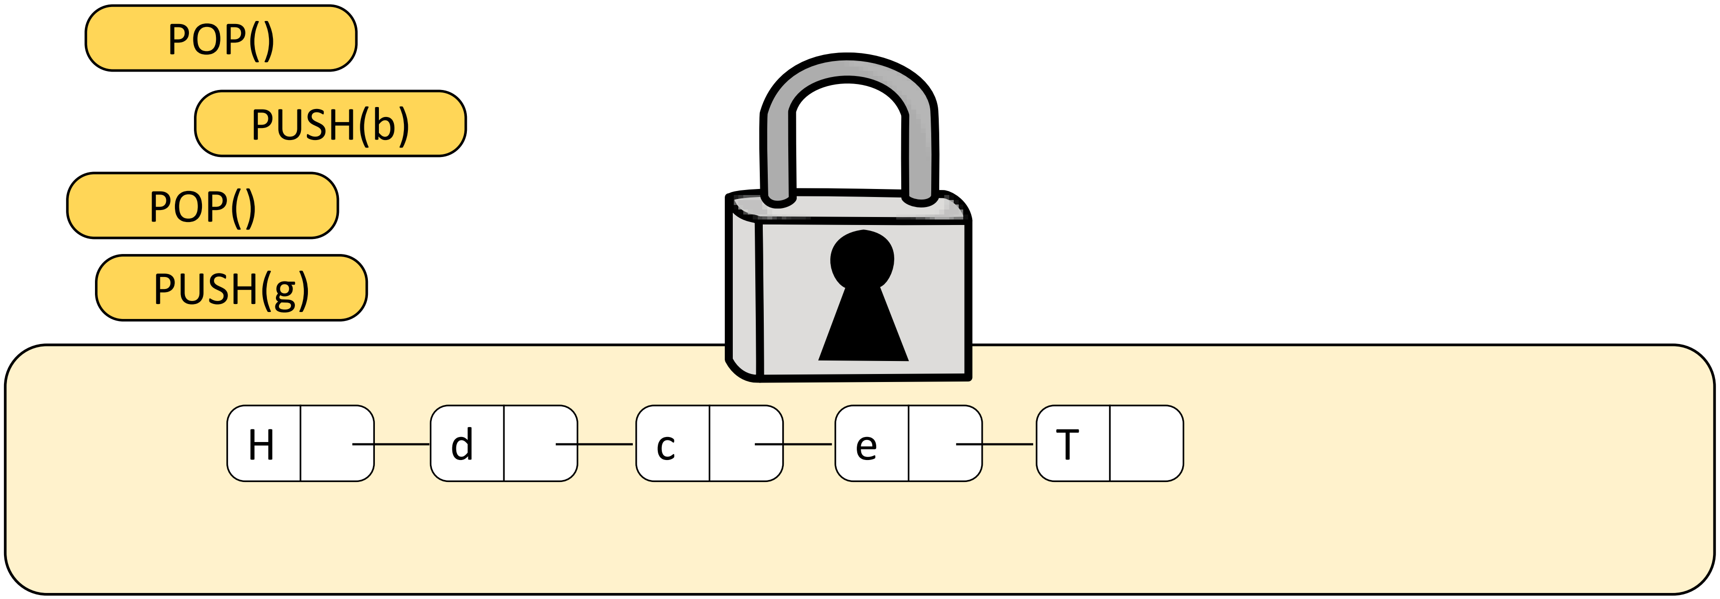
Stack implementation

- Stack methods:
  - `push(v)`
  - `pop()`
- Implemented as a linked list



Concurrent stack implementations

- Resort to a global lock



Read-Modify-Write

- RMW instructions allow to read memory and modify its content in an apparently instantaneous fashion.

```
RMW(MRegister *r, Function f){
  atomic{
    old = r;
    *r = f(r);
    return old;
  }
}
```

- Even conventional atomic Load and Store can be seen as RMW operations

Compare-And-Swap

- Compare-and-Swap (CAS) is an atomic instruction used in multithreading to achieve synchronization
  - It compares the contents of a memory area with a supplied value
  - If and only if they are the same
  - The contents of the memory area are updated with the new provided value
- Atomicity guarantees that the new value is computed based on up-to-date information
- If, in the meanwhile, the value has been updated by another thread, the update fails
- This instruction has been introduced in 1970 in the IBM 370 trying to limit as much as possible the use of spinlocks

Compare-And-Swap

- RMW instructions allow to read memory and modify its content in an apparently instantaneous fashion.

```
CAS(Mregister *r, Value old_value, Value new_value f){
  atomic{
     Value res = *r;
     if(*r == old_value) *r = new_value;
     return res;
  }
}
```

- CAS is implemented by x86 architectures (see CMPXCHG)
- gcc offers the `__sync_val_compare_and_swap` builtin

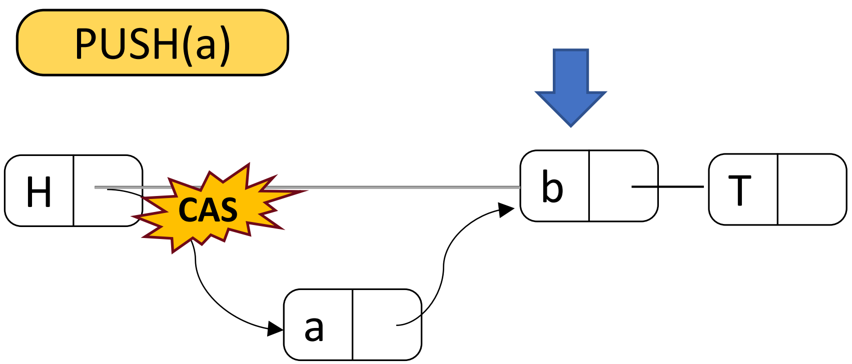
Attempt 1

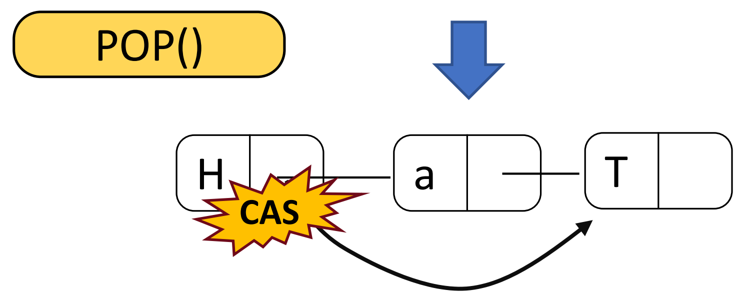
Push:

1. Get head next
2. Insert the new item with a CAS
3. If CAS fails, restart

Delete:

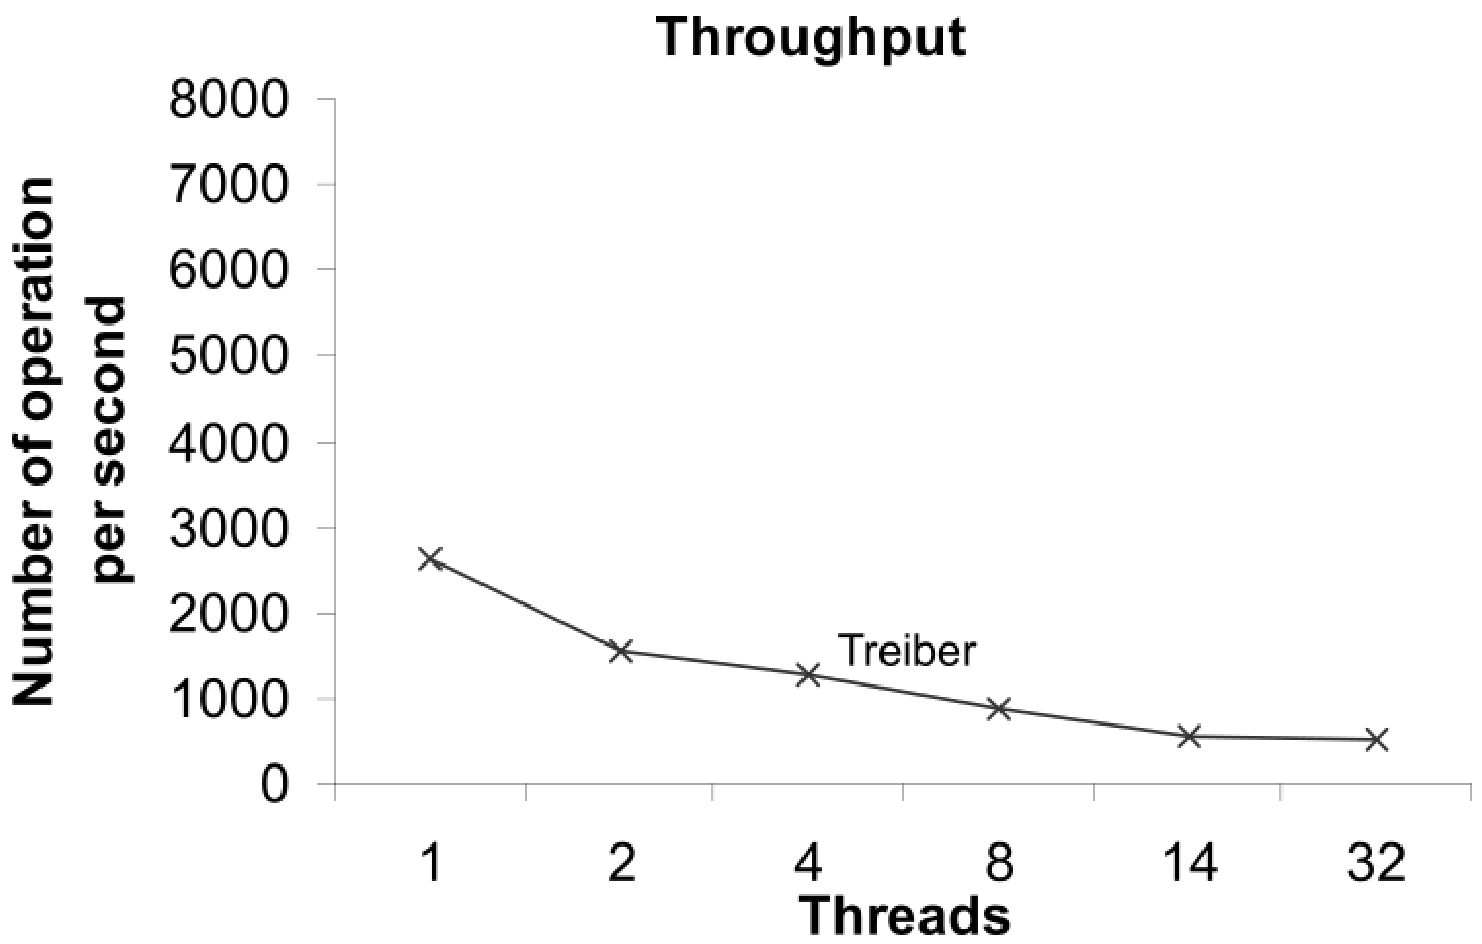
1. Get head next
2. Disconnect the item with a CAS
3. If CAS fails, restart





- Is it scalable?

Non-blocking stack – Attempt 2 [Treiber+BO]



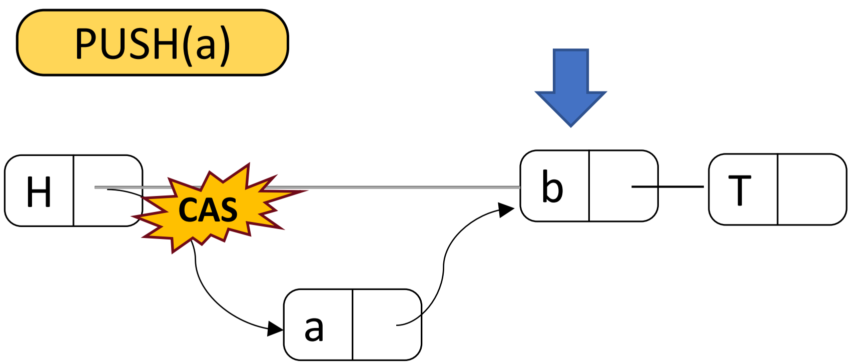
Non-blocking stack – Attempt 2 [Treiber+BO]

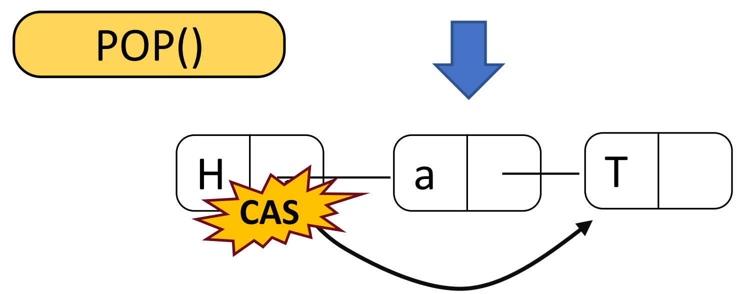
Push:

1. Get head next
2. Insert the new item with a CAS
3. If CAS fails, ~~restart~~ backoff and restart

Delete:

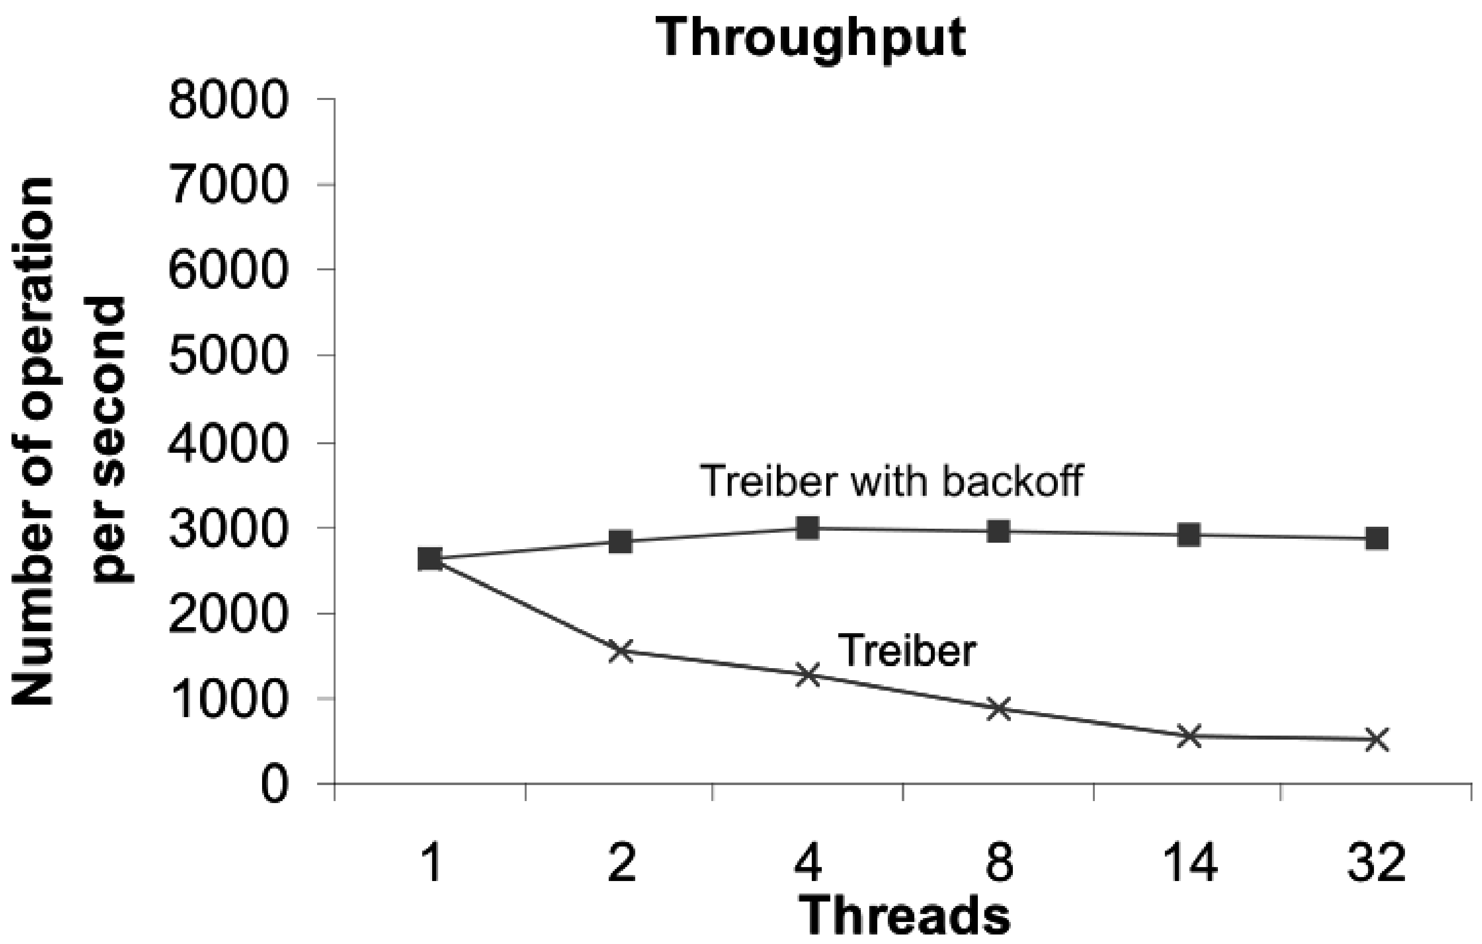
1. Get head next
2. Disconnect the item with a CAS
3. If CAS fails, ~~restart~~ backoff and restart





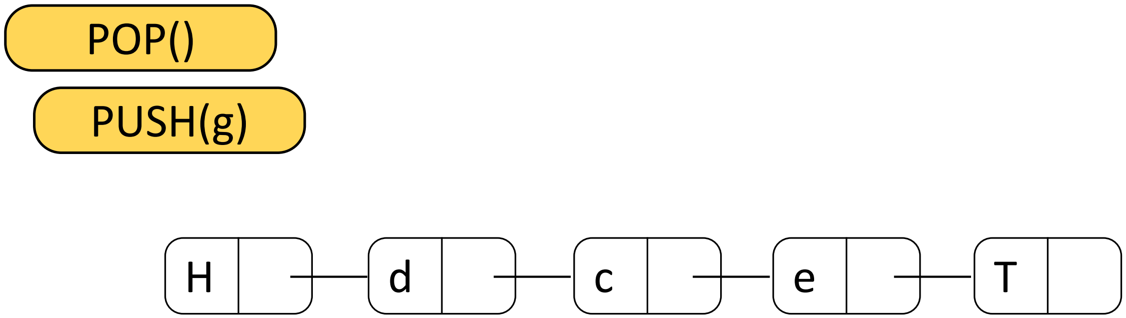
- Is it scalable?

Non-blocking stack – Attempt 2 [Treiber+BO]



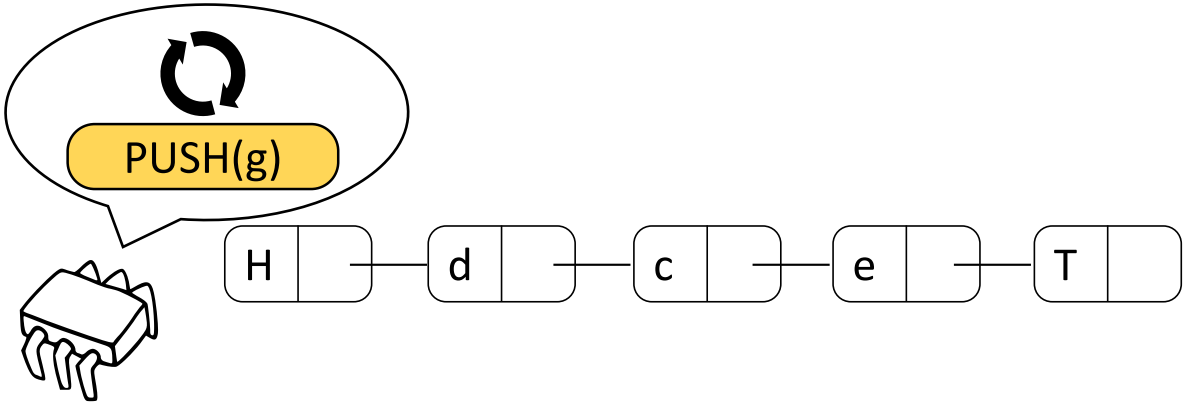
Concurrent stack implementations

- Resort to a global lock
  - Do not scale
- Resort to a naïve non-blocking approach
  - Do not scale
- Resort to a naïve non-blocking approach + Back off
  - Do not scale, but conflict resilient
- How achieve scalability? Make back-off times useful



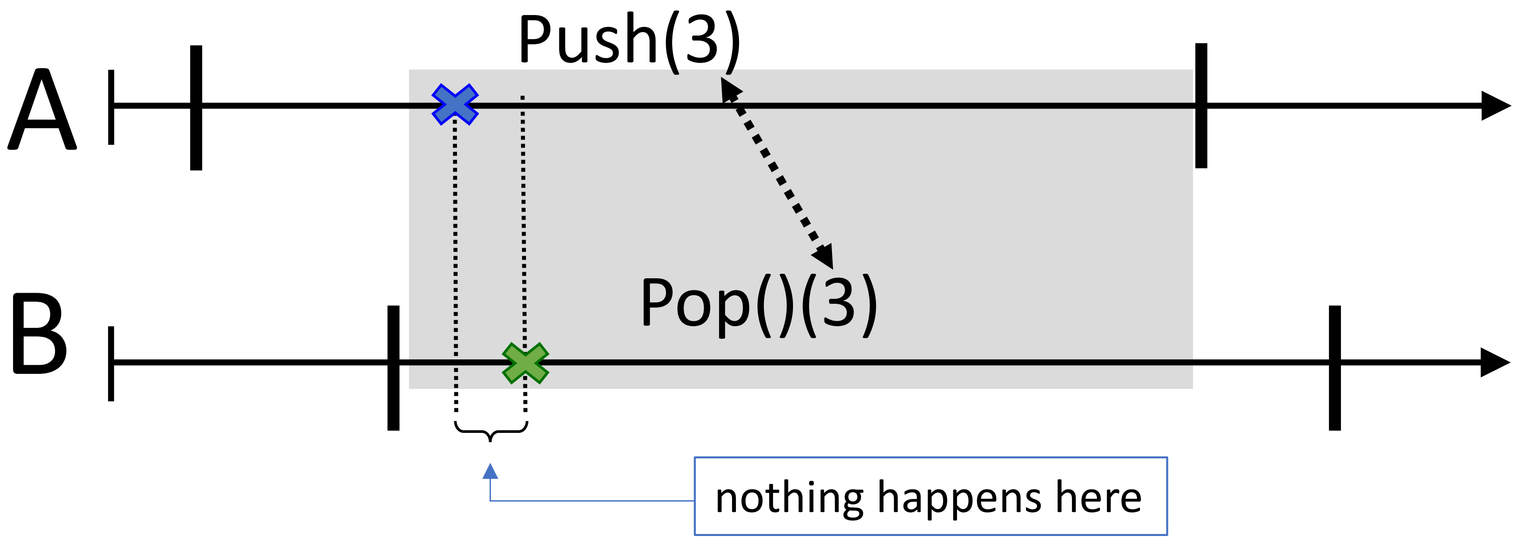
Non-blocking stack – Attempt 3

- How to take advantage of back-off times?



Observation

- Concurrent matching push/pop pairs are always linearizable

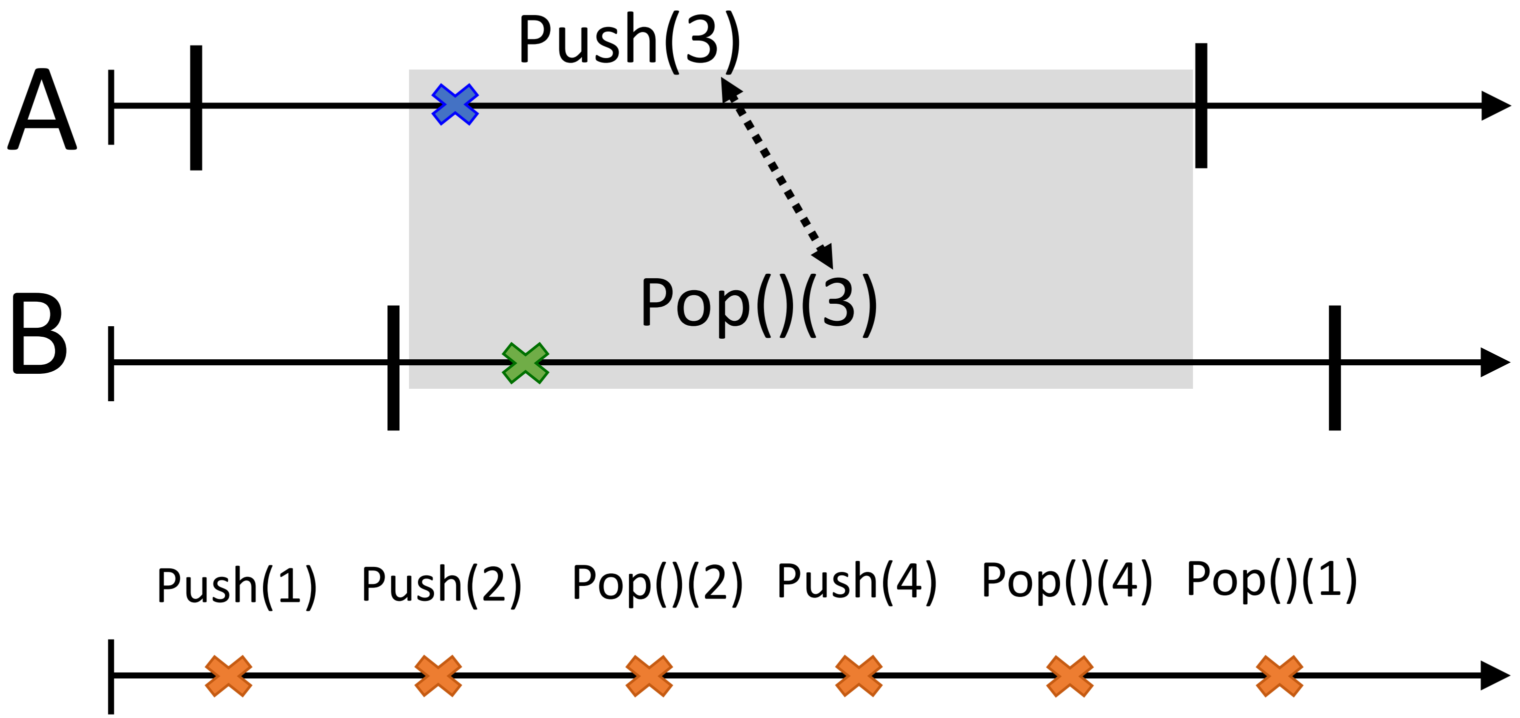


- A push A and a pop B are:
  - concurrent to each other
  - B returns the item inserted by A

⇒ we can always take two points such that:
  - A is the last one to insert an item before A linearizes
  - B appears to extract the last item inserted (by A)

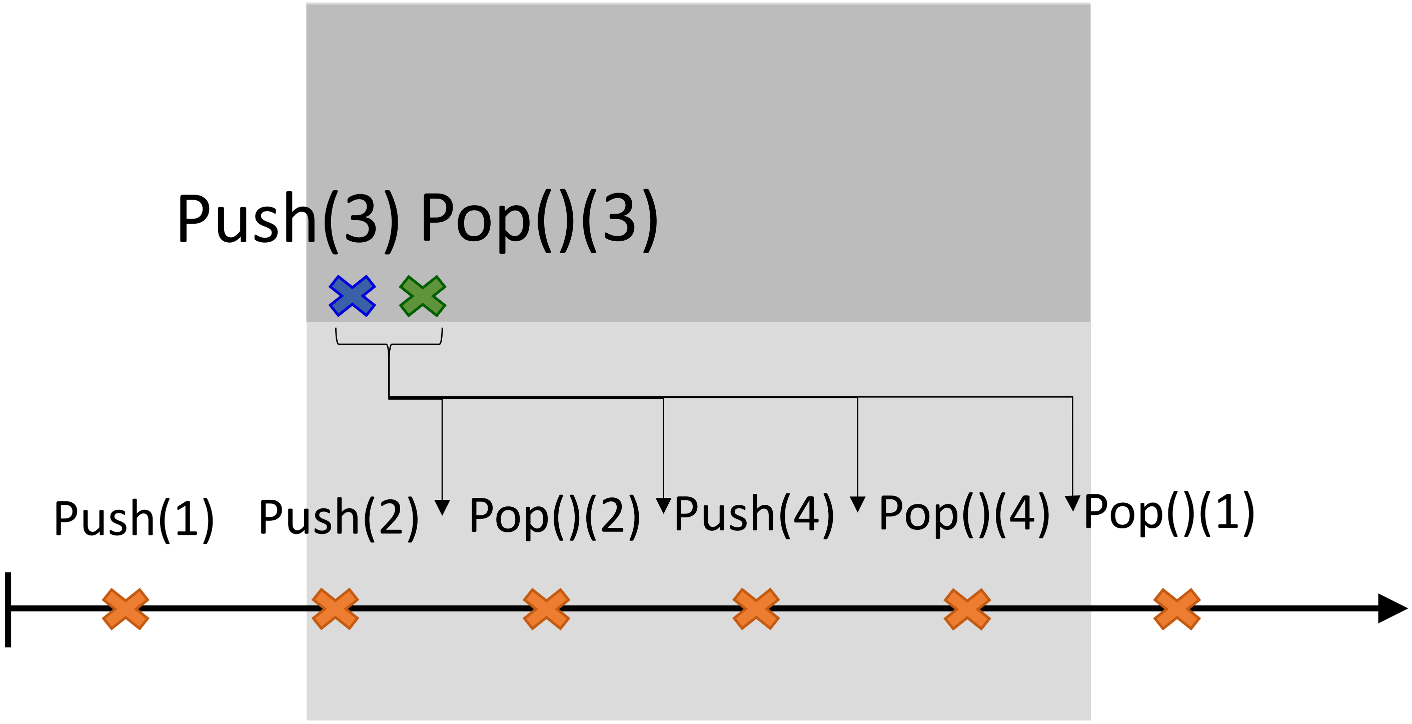
Observation

- Concurrent matching push/pop pairs are always linearizable



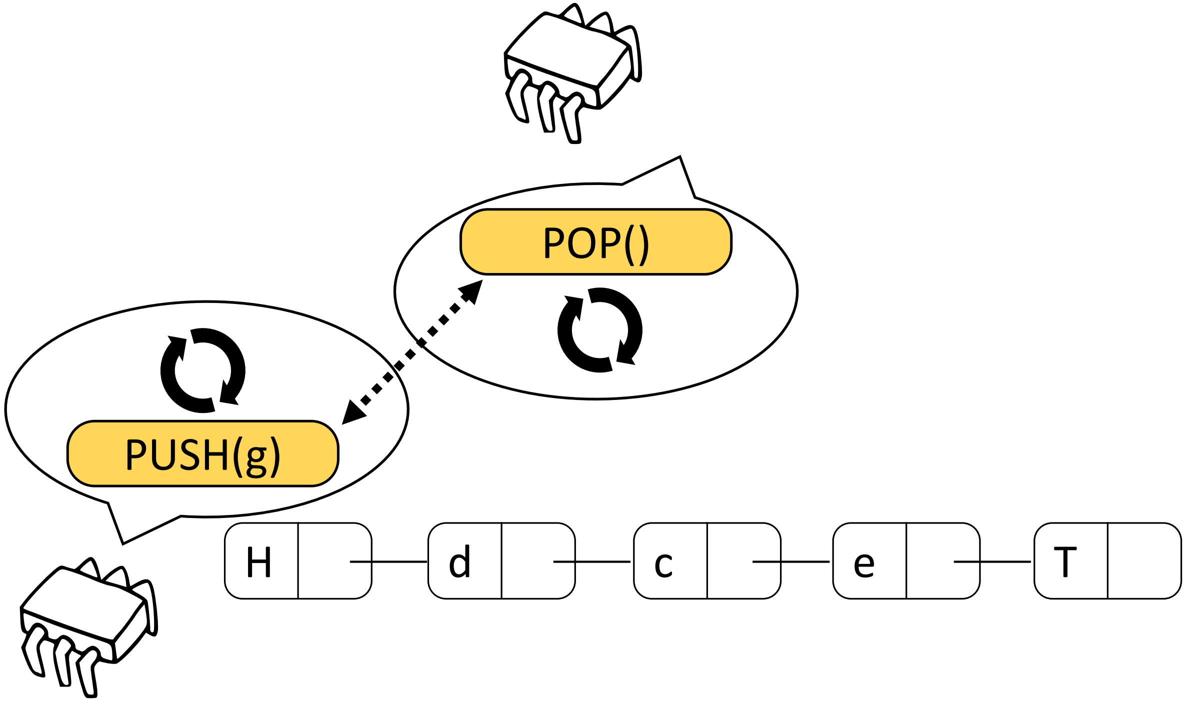
Observation

- Concurrent matching push/pop pairs are always linearizable



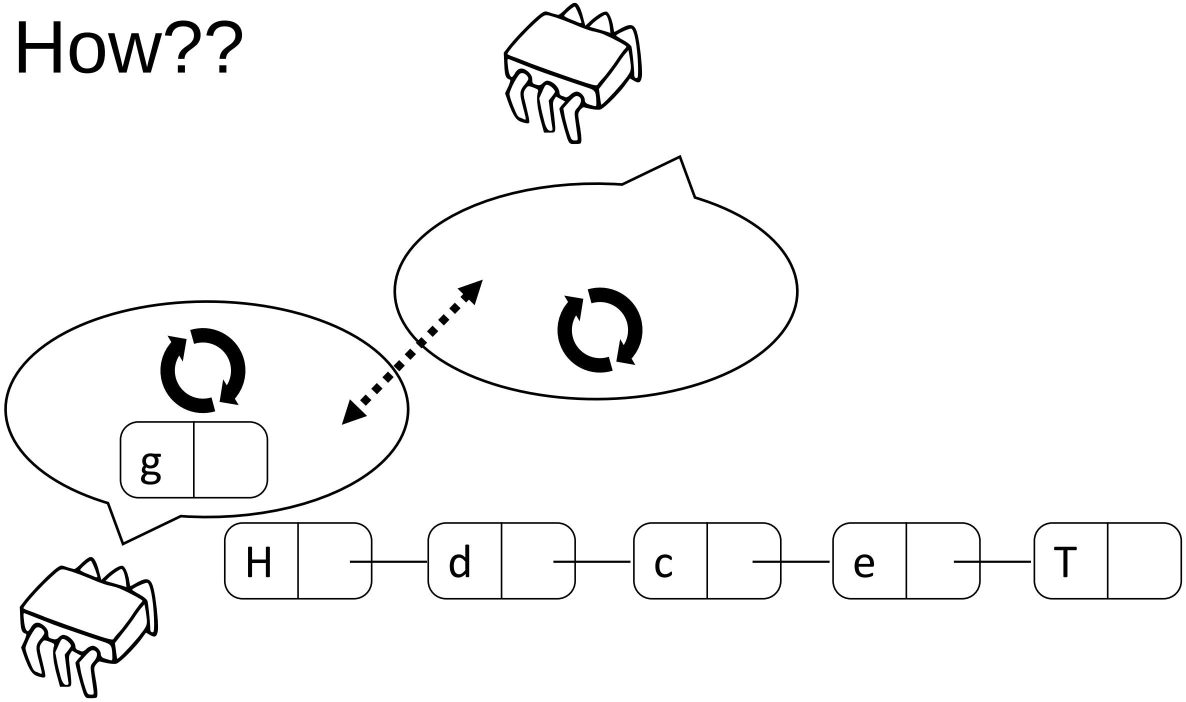
Non-blocking stack – Attempt 3

- How to take advantage of back-off times?
- Hope that an opposite operation arrives while waiting
- Match the two without interacting with the stack



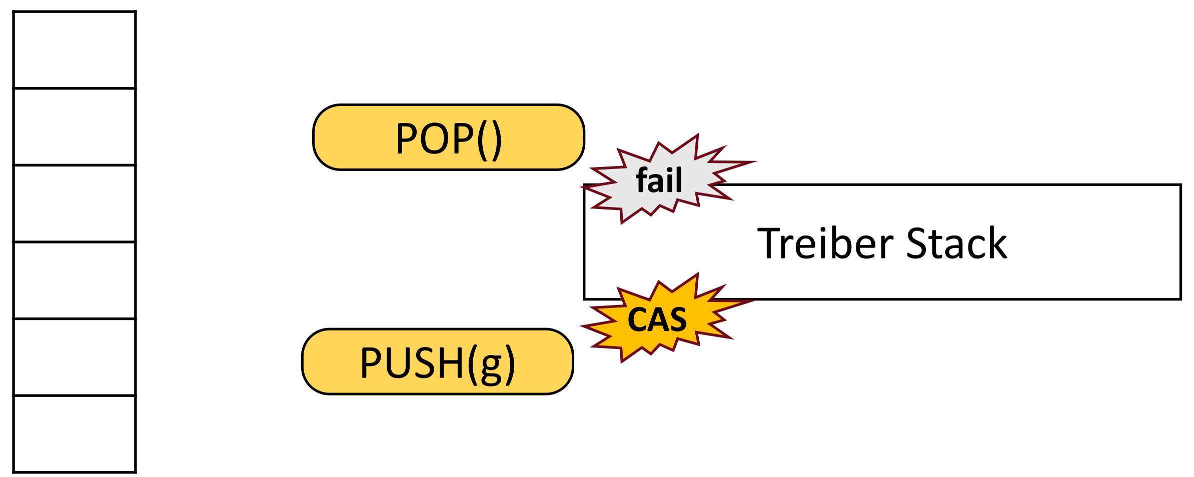
Non-blocking stack – Attempt 3

- How to take advantage of back-off times?
- Hope that an opposite operation arrives while waiting
- Match the two without interacting with the stack
- How??



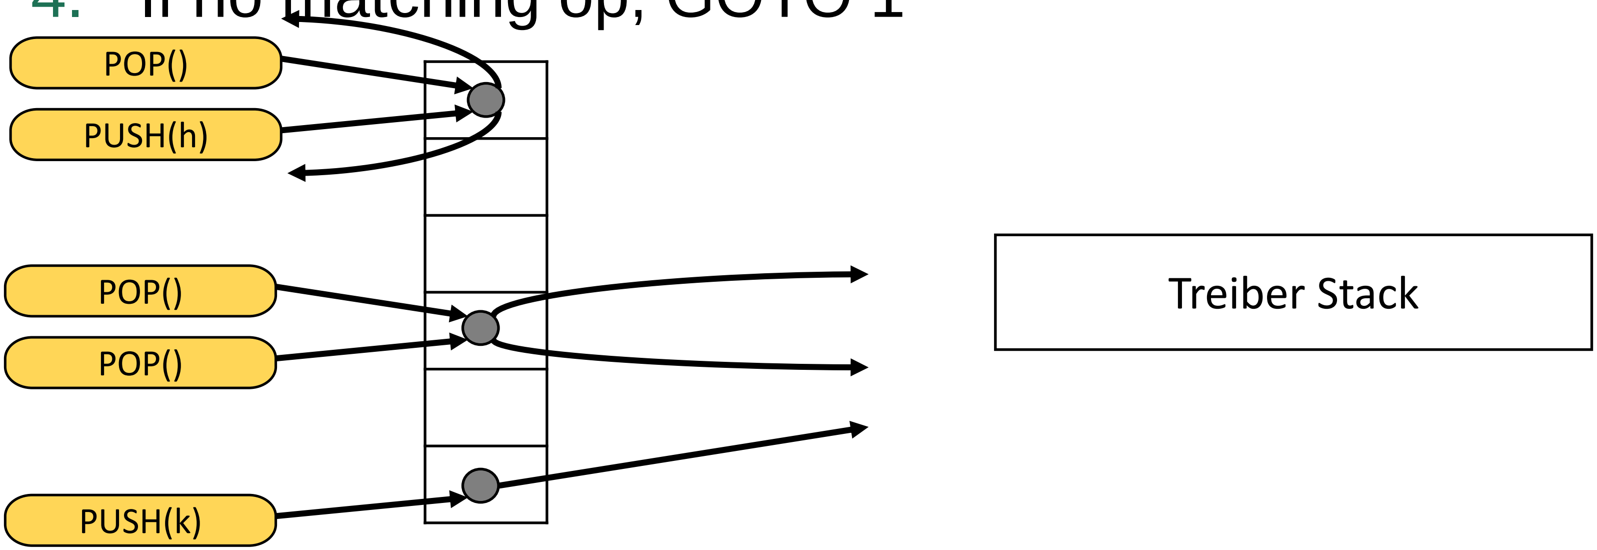
Non-blocking stack – Elimination stack

- Pair the Treiber stack with an array
- Algorithm:
    1. Update the original stack via CAS
    2. If CAS fails, publish the operation in a random cell of the array

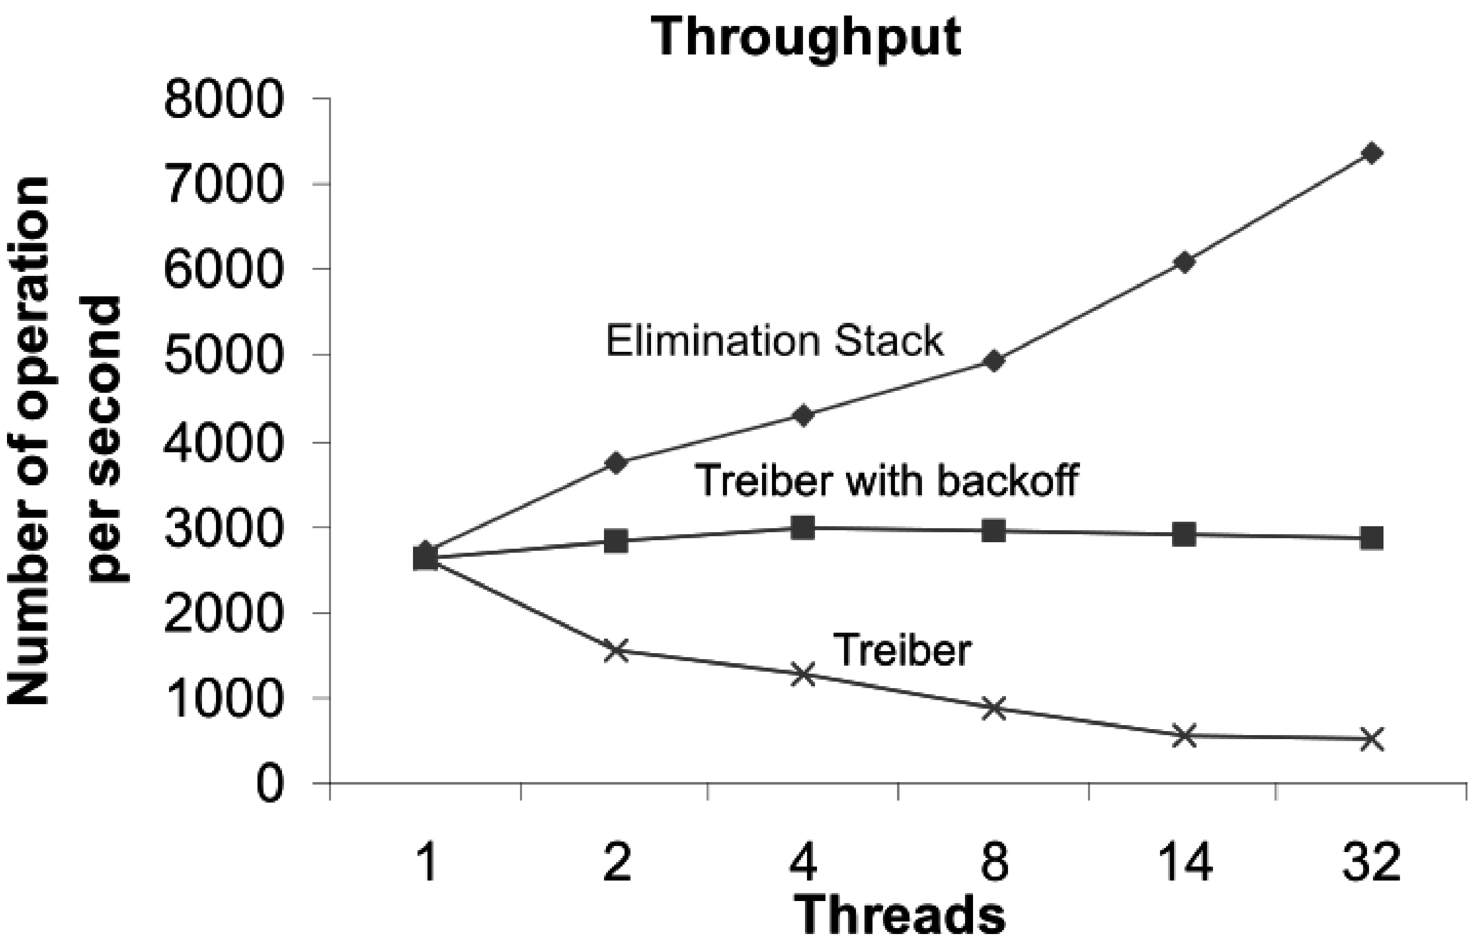


Non-blocking stack – Elimination stack

- Pair the Treiber stack with an array
- Algorithm:
  1. Update the original stack via CAS
  2. If CAS fails, publish the operation in a random cell of the array
  3. Wait for a matching operation
  4. If no matching op, GOTO 1



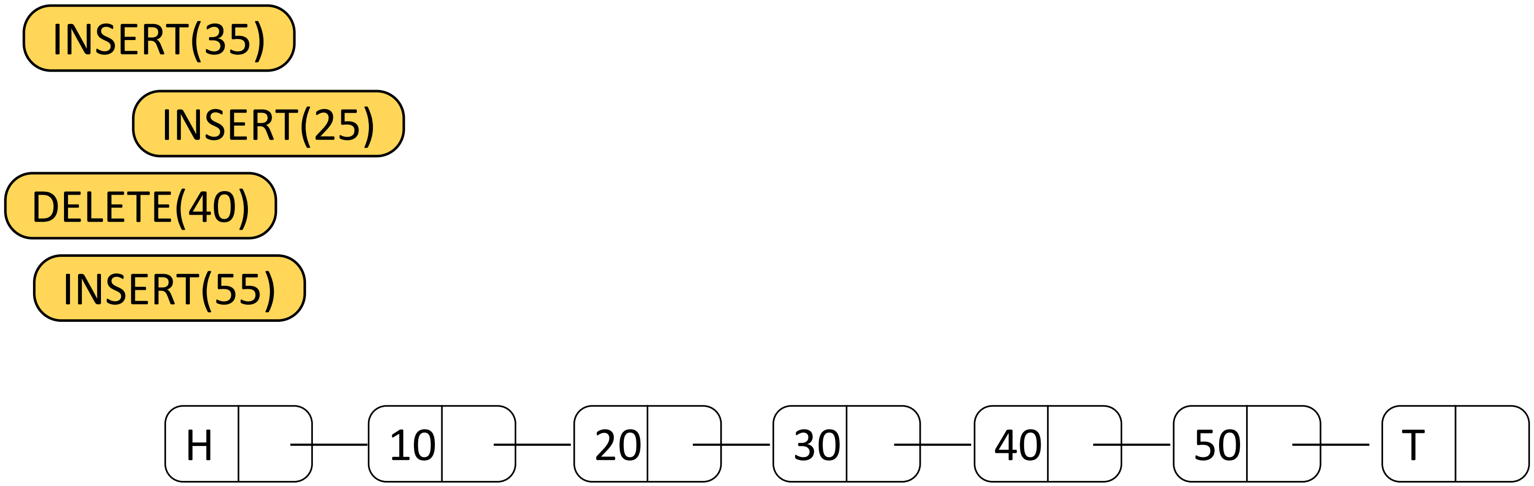
Non-blocking stack – Attempt 3



Concurrent Data Structures: Sets

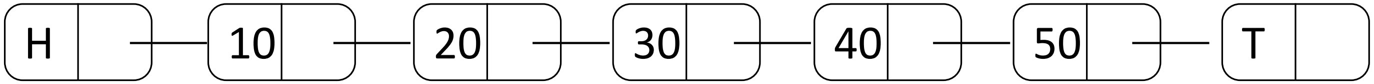
Set implementations

- Set methods:
  - `insert(k)`
  - `delete(k)`
  - ~~`find(k)`~~
- Implemented as an ordered linked list

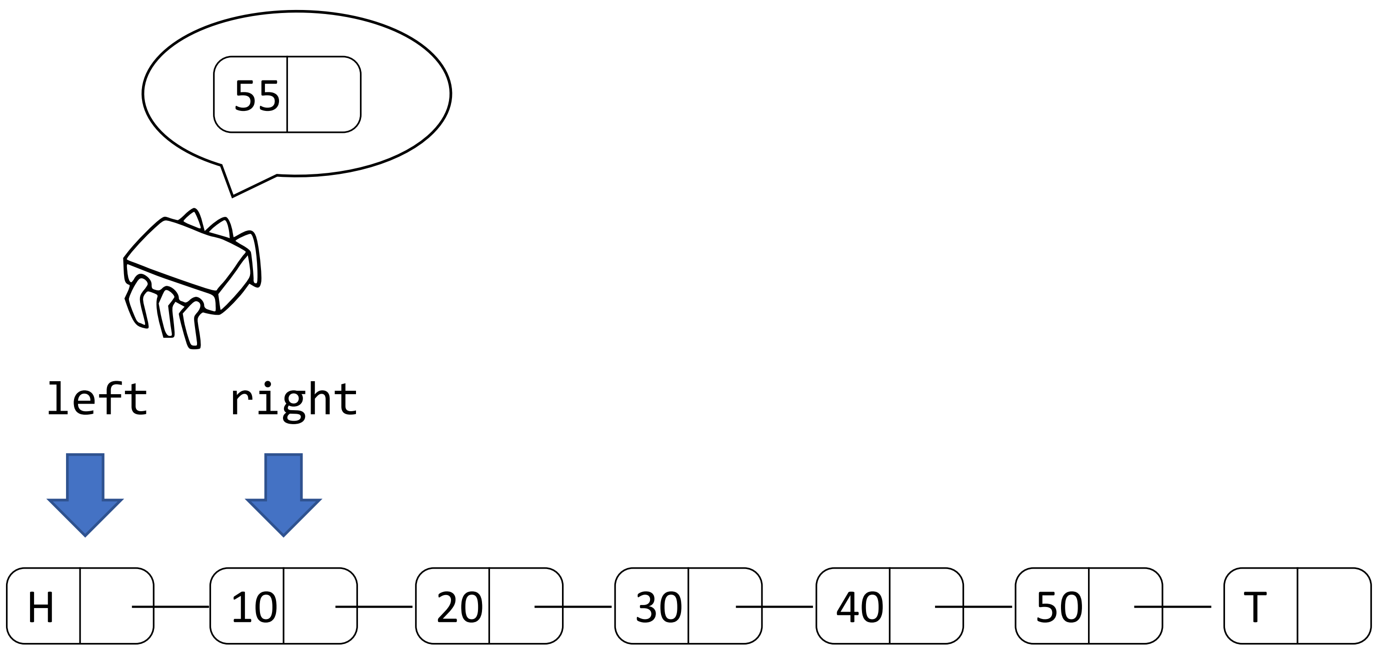


Insert algorithm

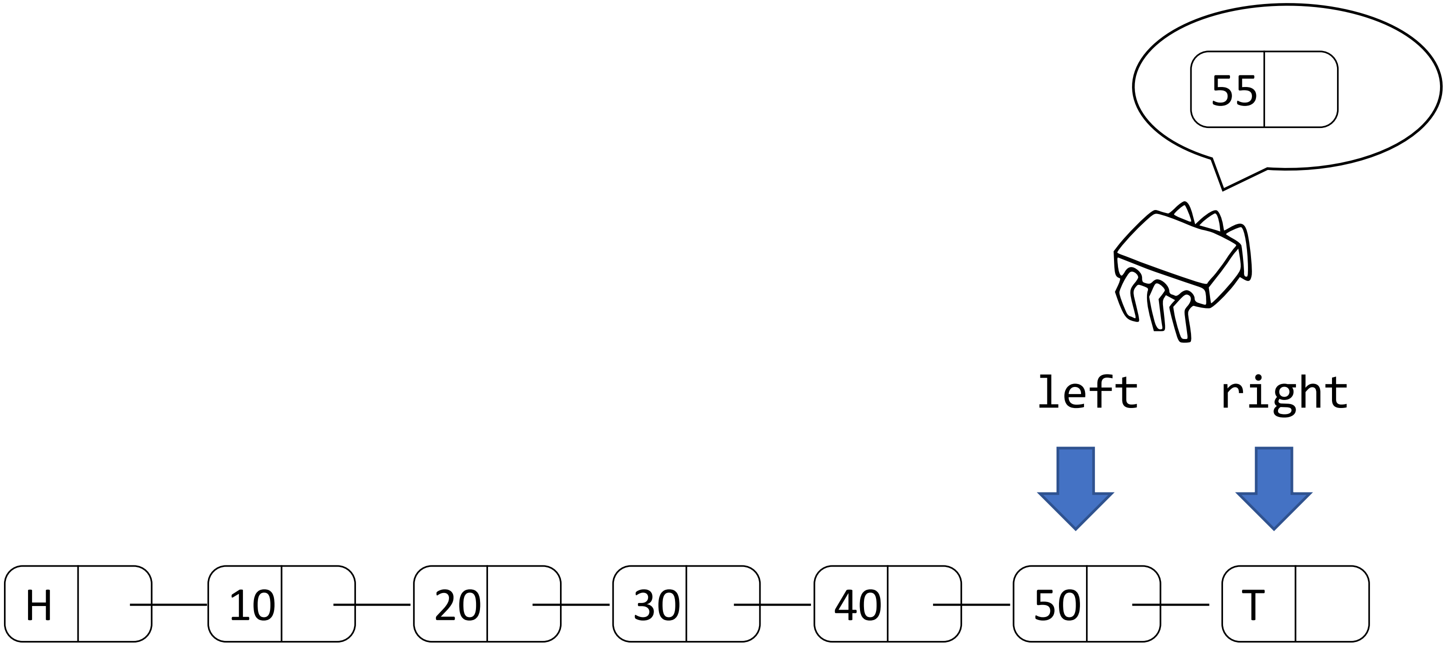
INSERT(55)



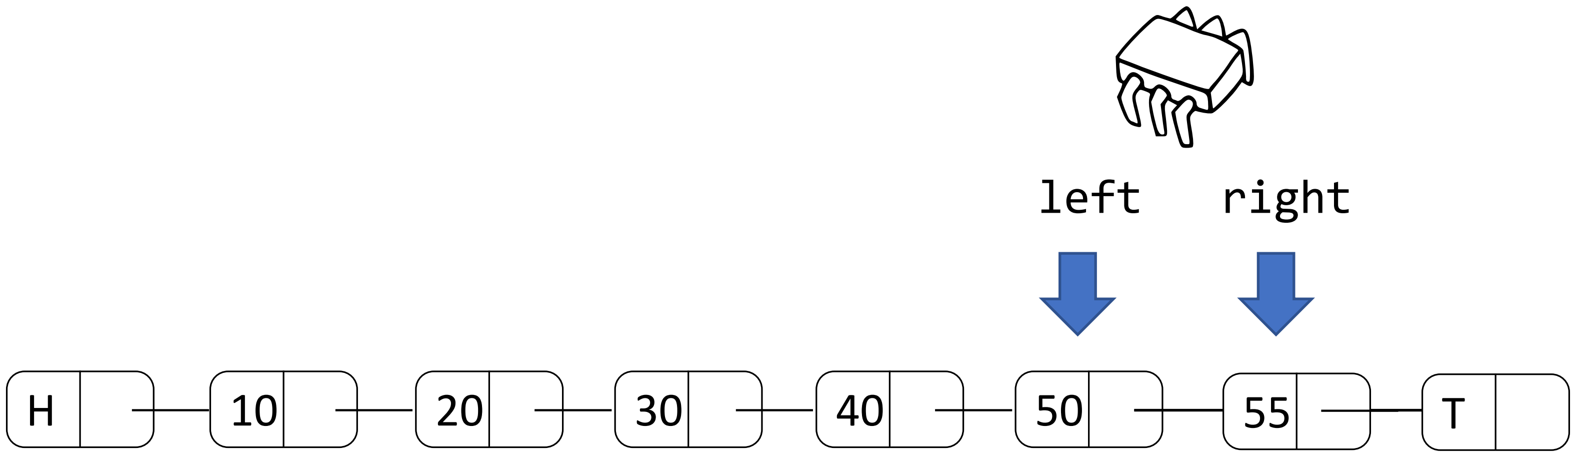
Insert algorithm



Insert algorithm

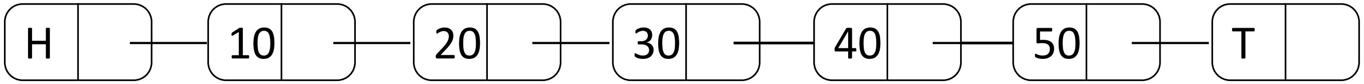


Insert algorithm

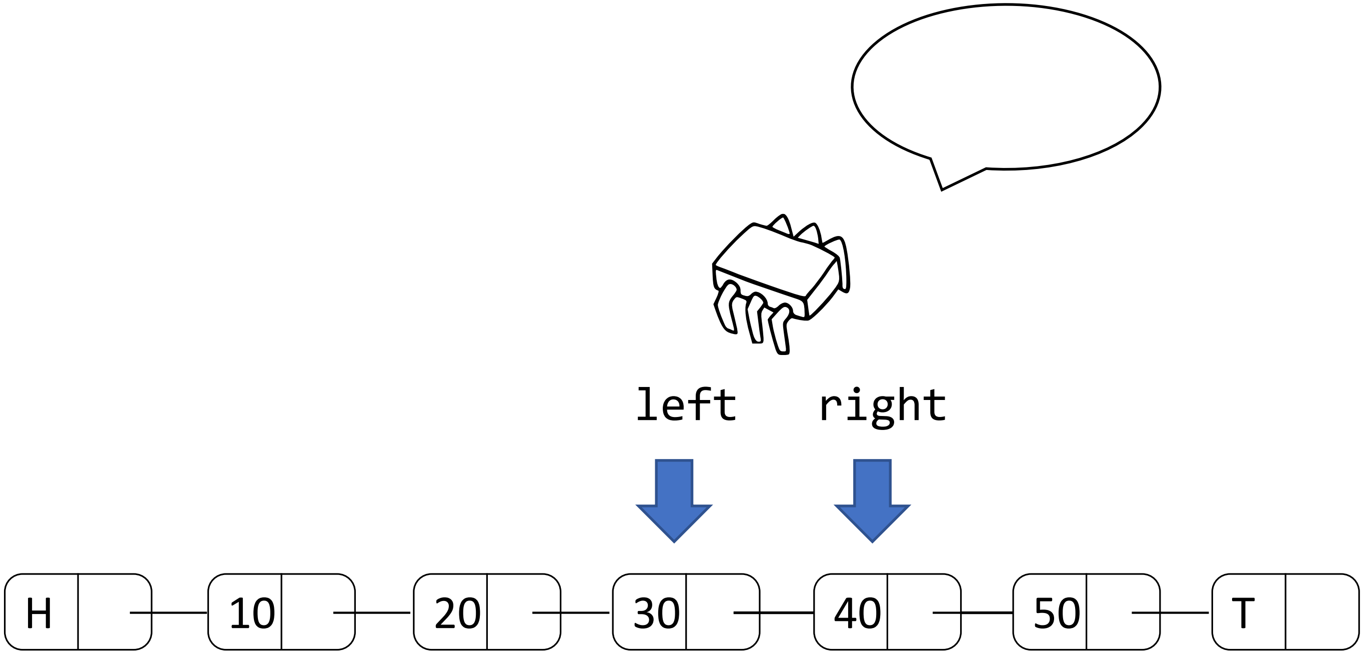


Delete algorithm

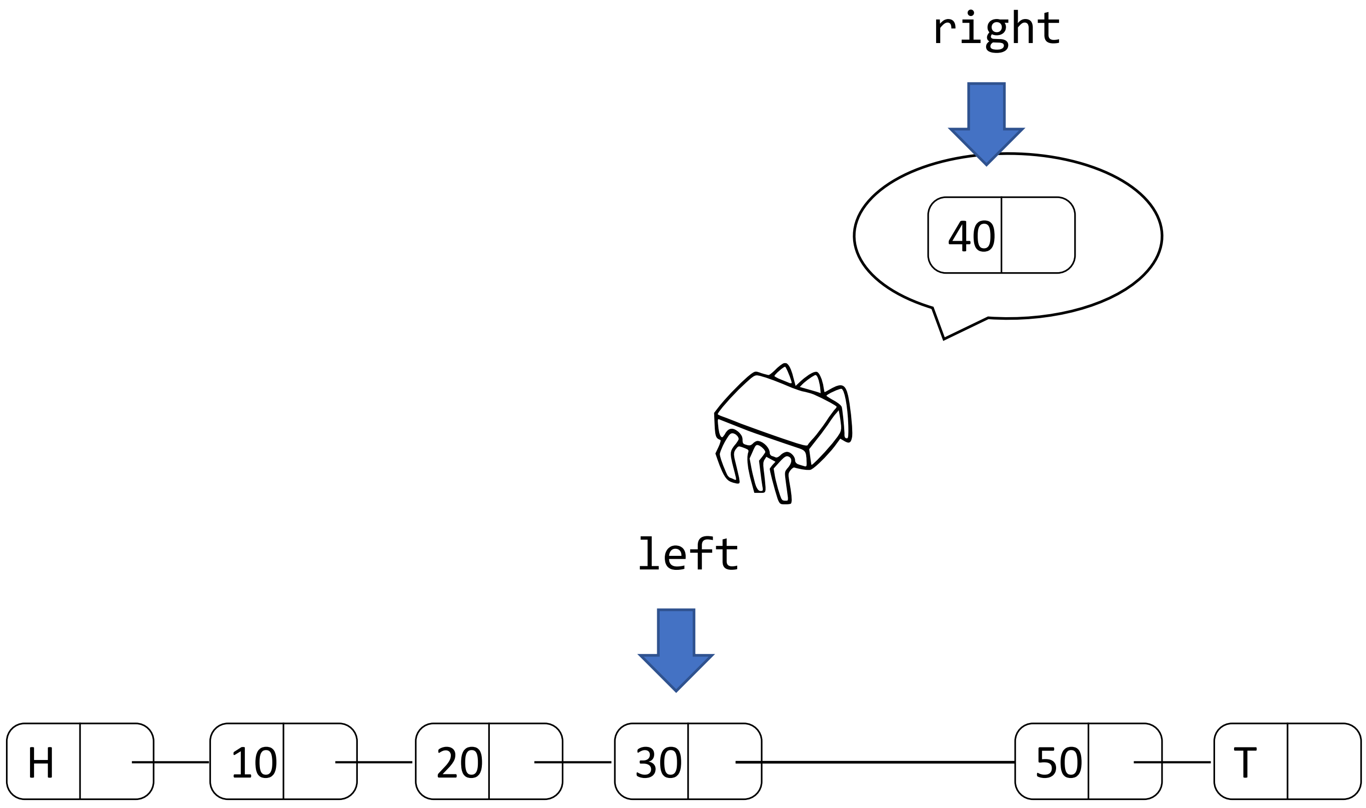
DELETE(40)



Delete algorithm



Delete algorithm



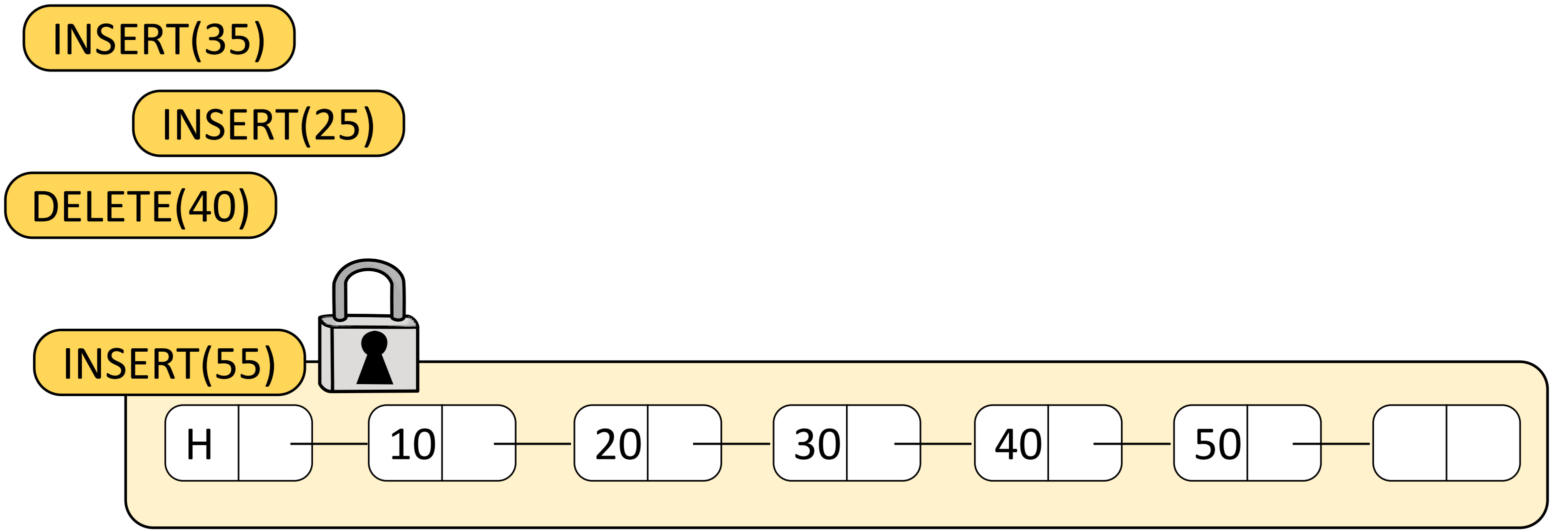
Sequential set implementation

```
bool do_operation(int k, int op_type){
  bool res = true;
  node *l,*r;
  l = search(k, &r);
  switch(op_type){
    case(INSERT):
      if(r->key == k)
        res = false;
      else
        l->next = new node(k,r);
      break;
    case(DELETE):
      if(r->key == k)
        l->next = r->next;
      else
        res = false;
      break;
  }
  return res;
}
```

```
node* search(int k, node **r){
  node *l, *r_next;
  l = set->head;
  *r = l->next;
  r_next = (*r)->next;
  while((*r)->key < k){
    l = *r;
    *r = r_next;
    r_next = (*r)->next;
  }
}
```

Concurrent set – Attempt 1

- PESSIMISTIC approach
- Synchronize via global lock

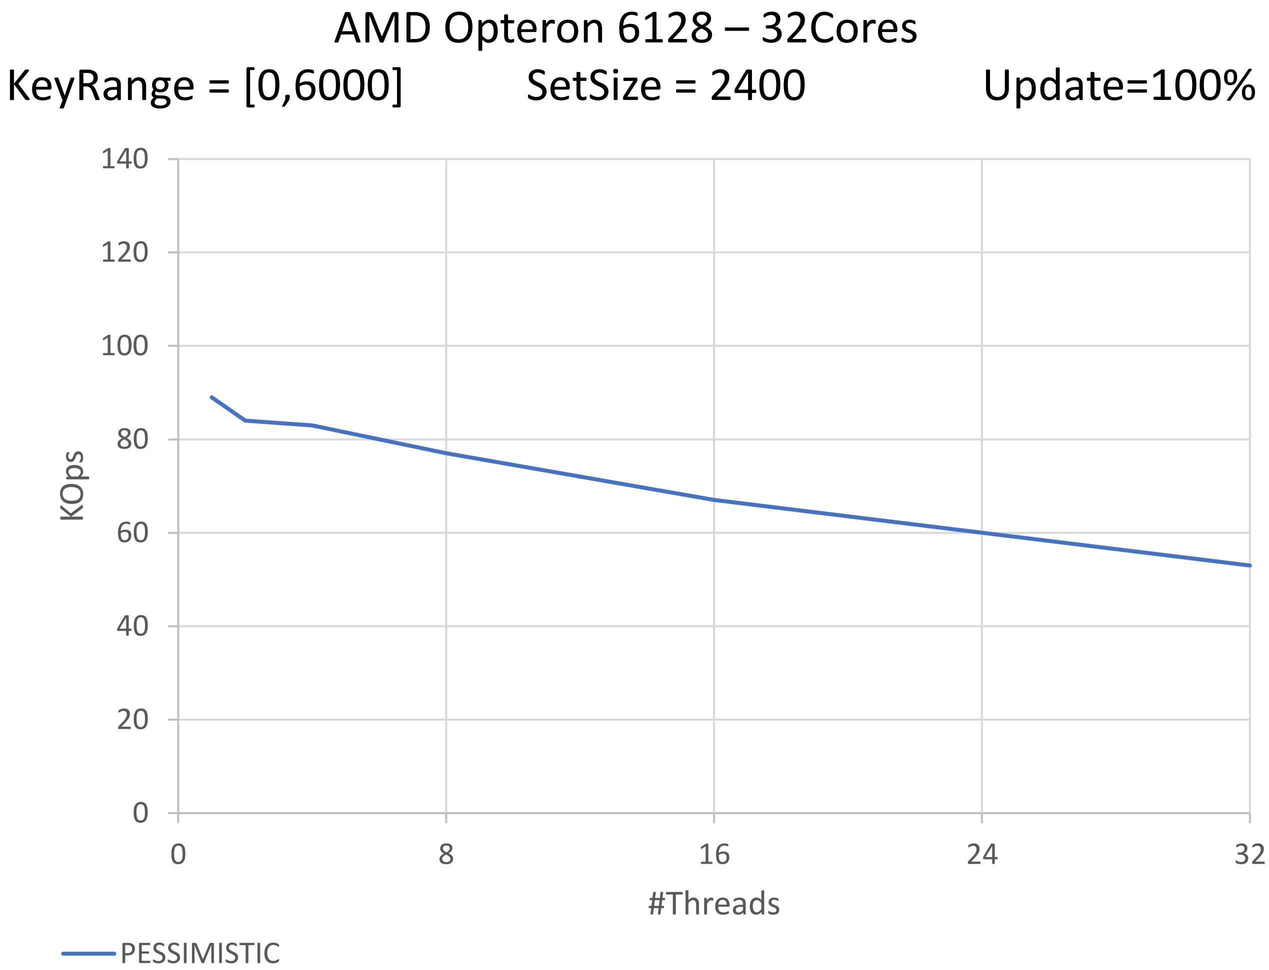


Concurrent set – Attempt 1 (SRC)

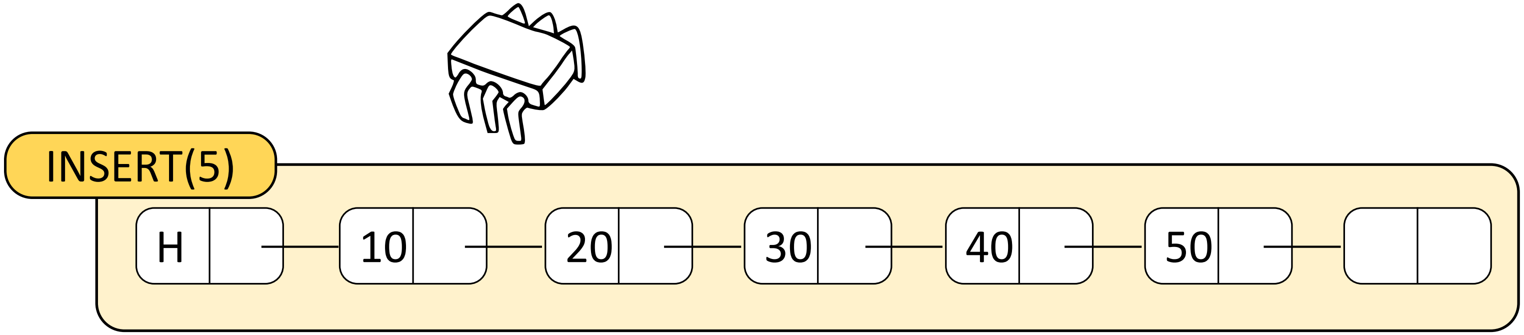
```
bool do_operation(int k, int op_type){
  bool res = true;
  node *l,*r;
  LOCK(&glock);
  l = search(k, &r);
  switch(op_type){
    case(INSERT):
      if(r->key == k)
        res = false;
      else
        l->next = new node(k,r);
      break;
    case(DELETE):
      if(r->key == k)
        l->next = r->next;
      else
        res = false;
      break;
  }
  UNLOCK(&glock);
  return res;
}
```

```
node* search(int k, node **r){
  node *l, *r_next;
  l = set->head;
  *r = l->next;
  r_next = (*r)->next;
  while((*r)->key < k){
    l = *r;
    *r = r_next;
    r_next = (*r)->next;
  }
}
```

Concurrent set – Attempt 1



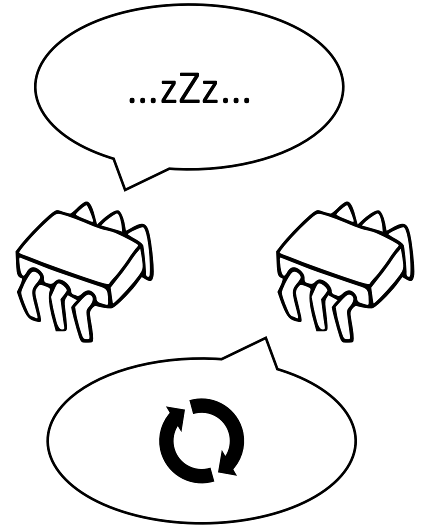
Concurrent set – Attempt 1

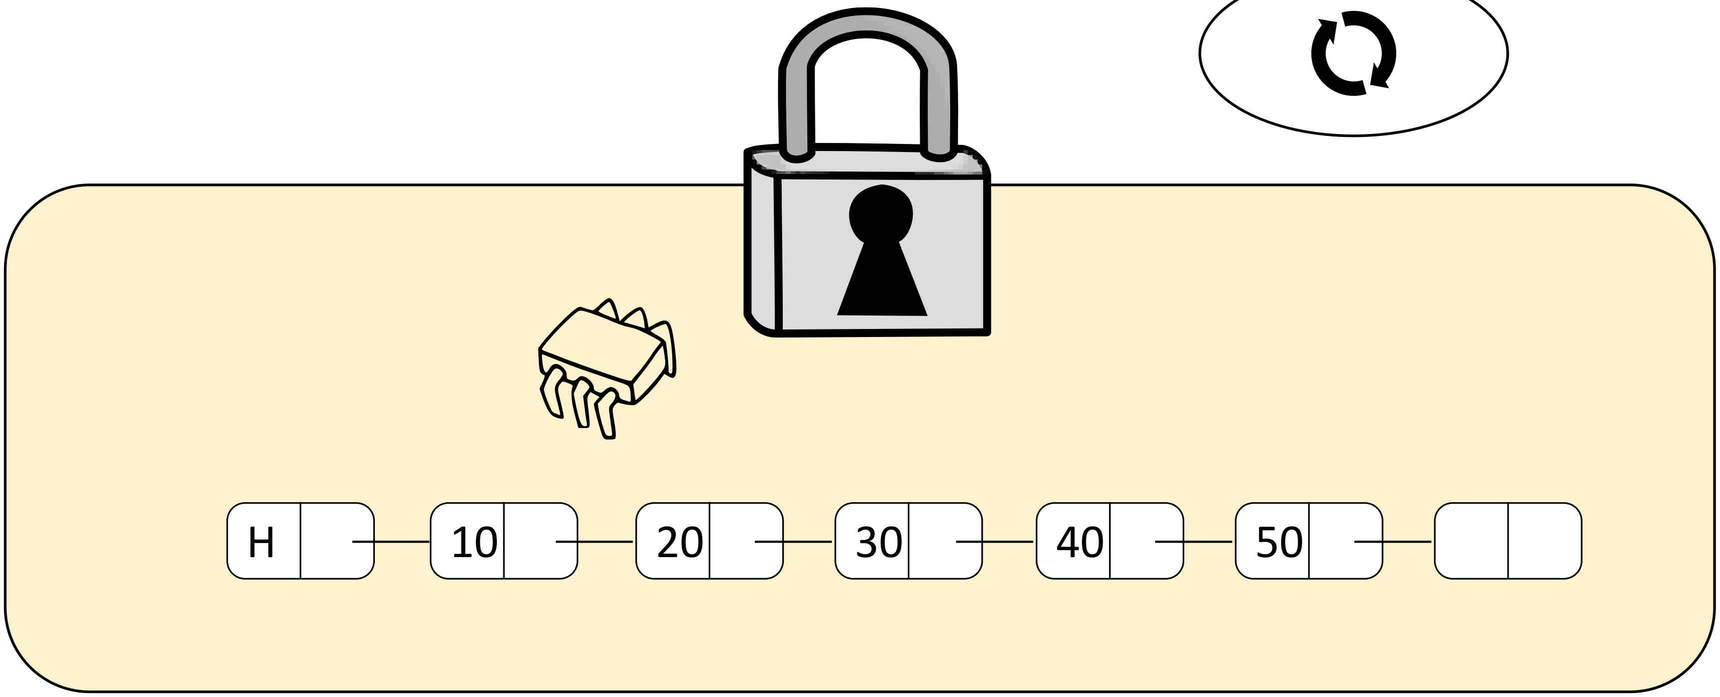


Concurrent set – Attempt 1

- PESSIMISTIC approach
- Synchronize via global lock

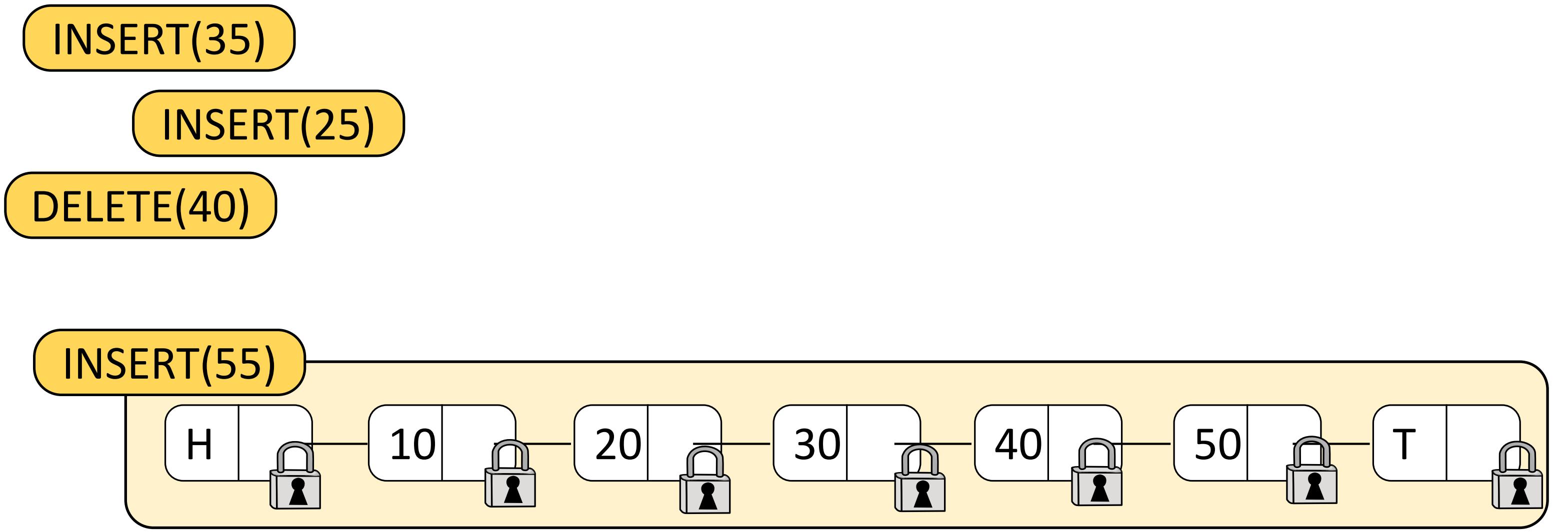
⇒NO SCALABILITY!





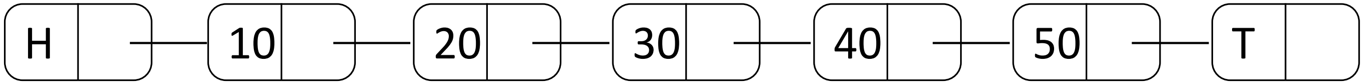
Concurrent set – Attempt 2

- Fine-grain approach
- Each node has its own lock
- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor



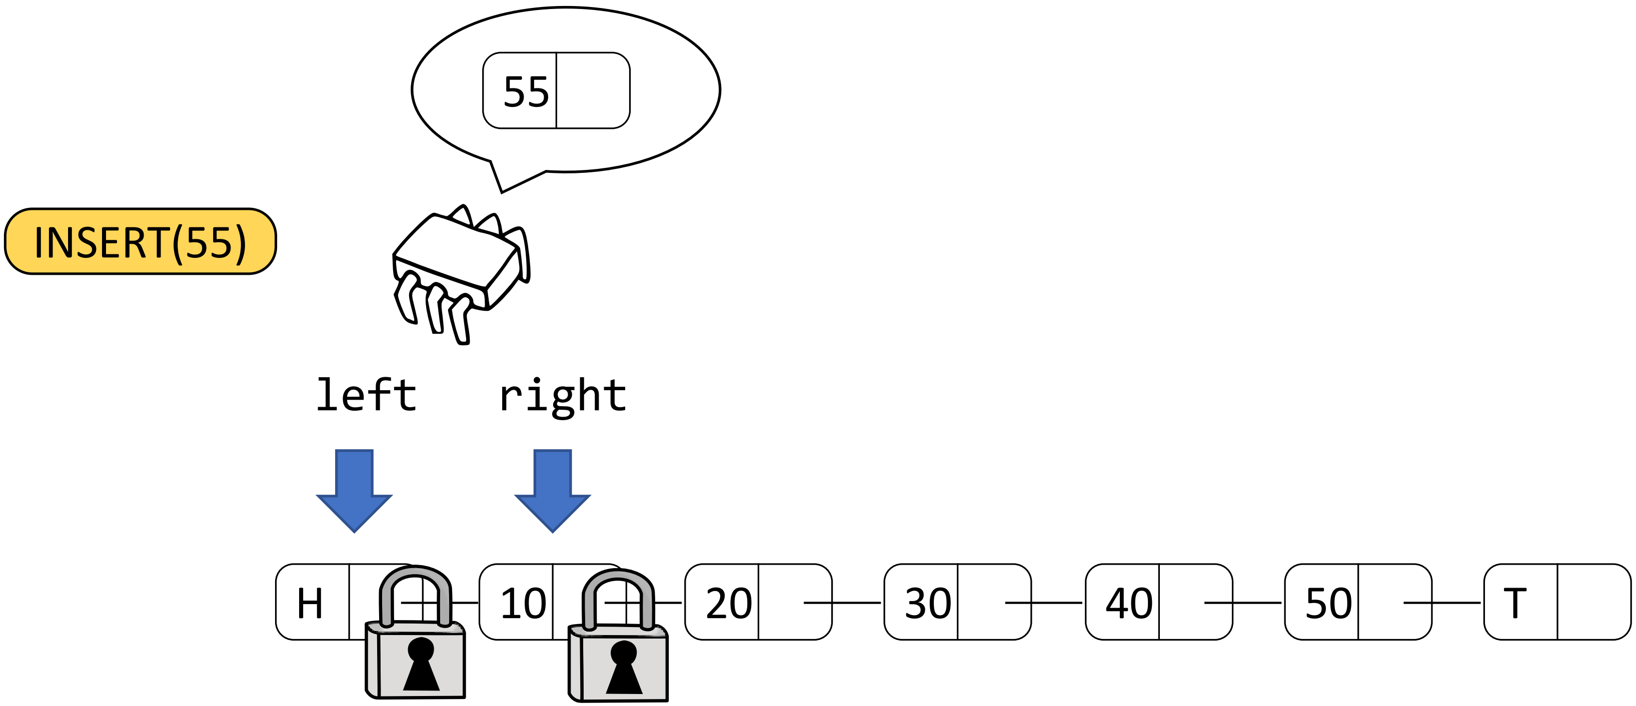
Search algorithm

INSERT(55)



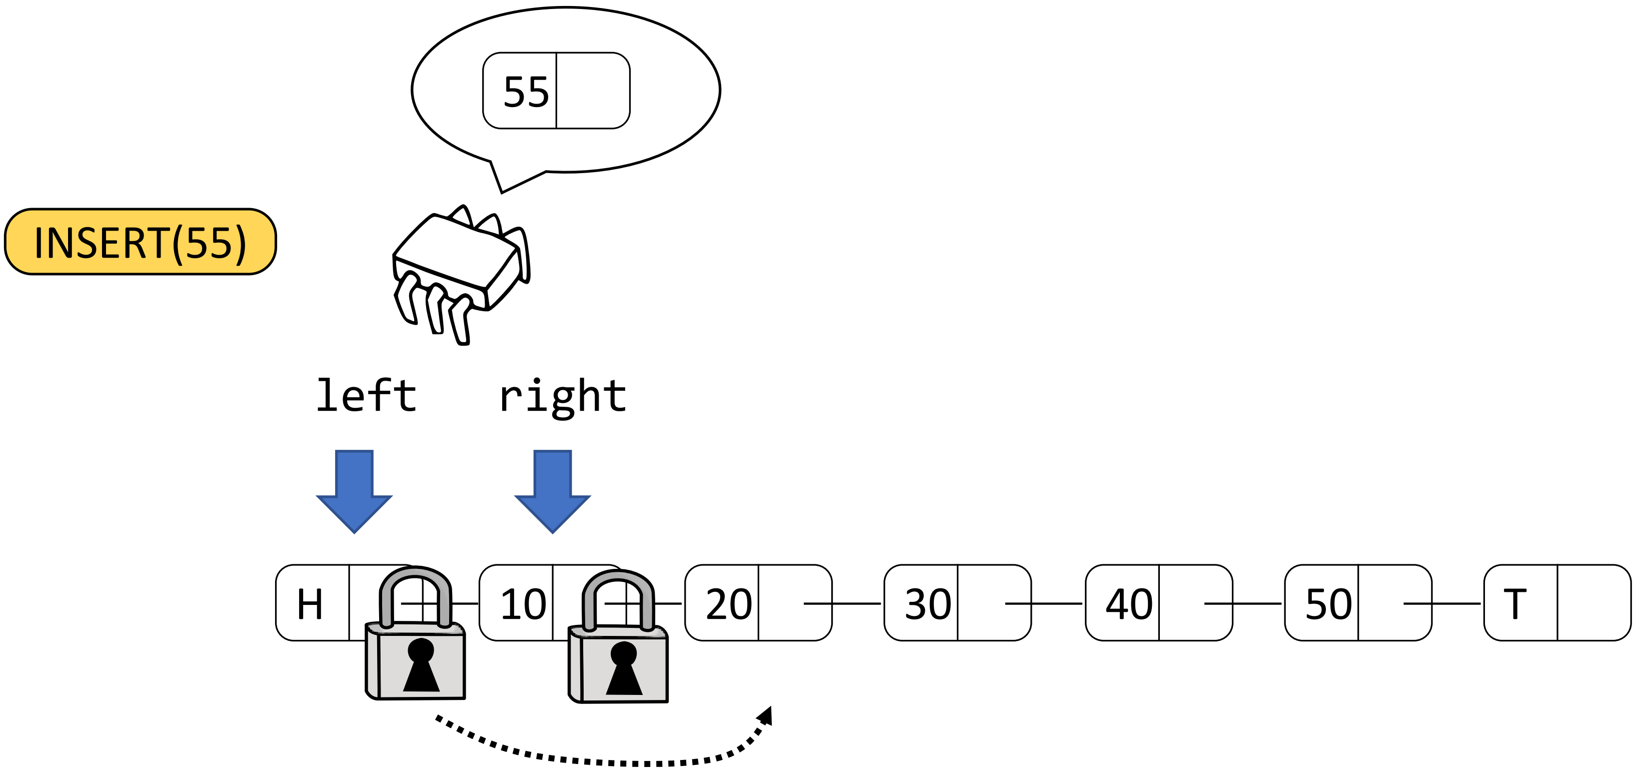
Search algorithm

- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor



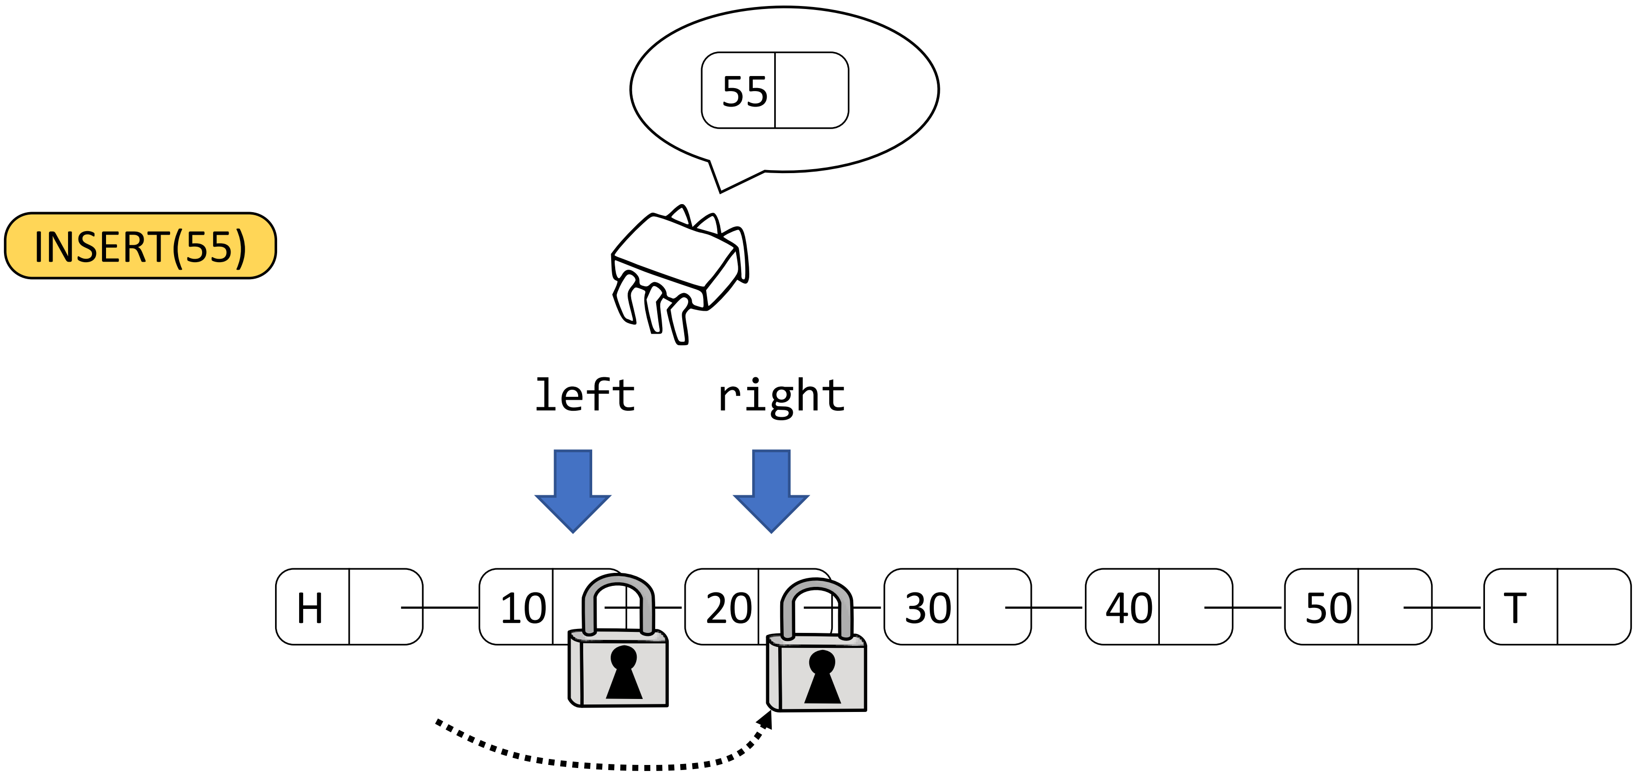
Search algorithm

- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor



Search algorithm

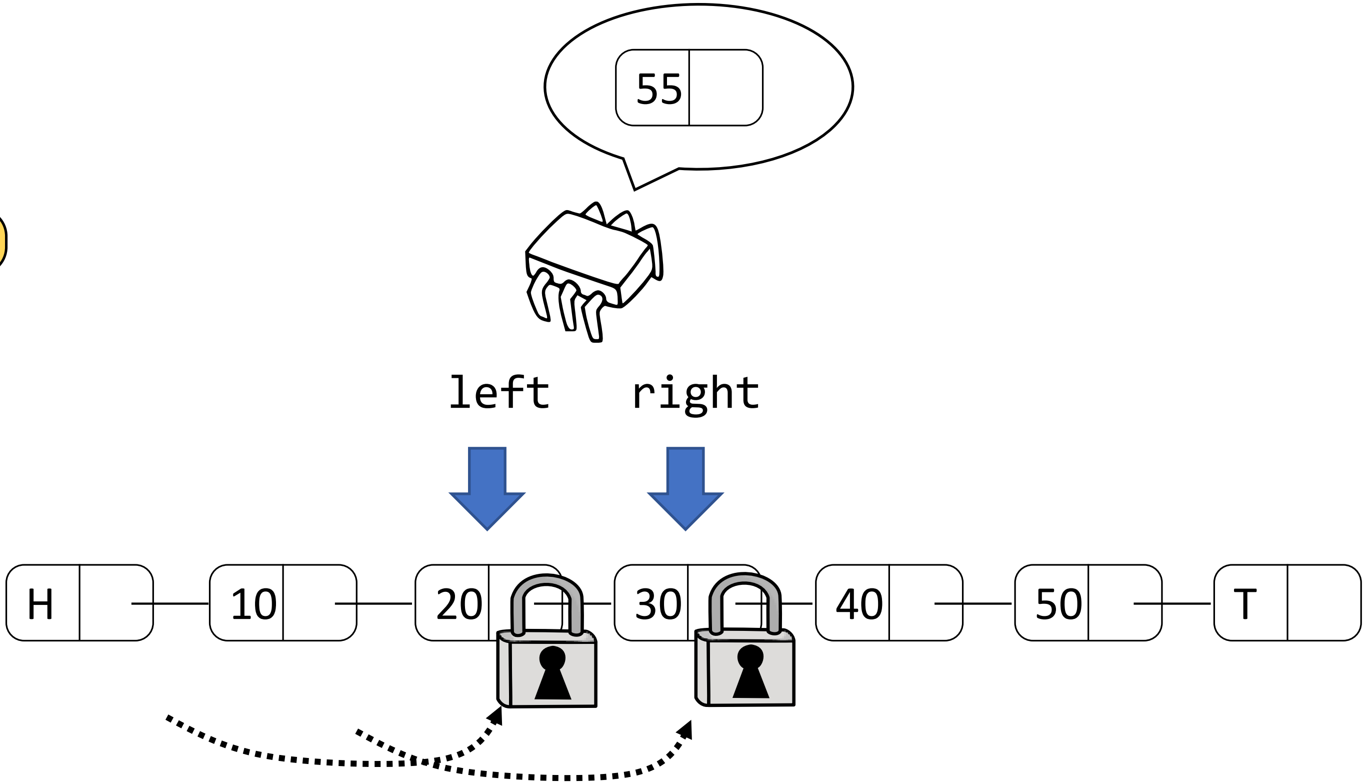
- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor



Search algorithm

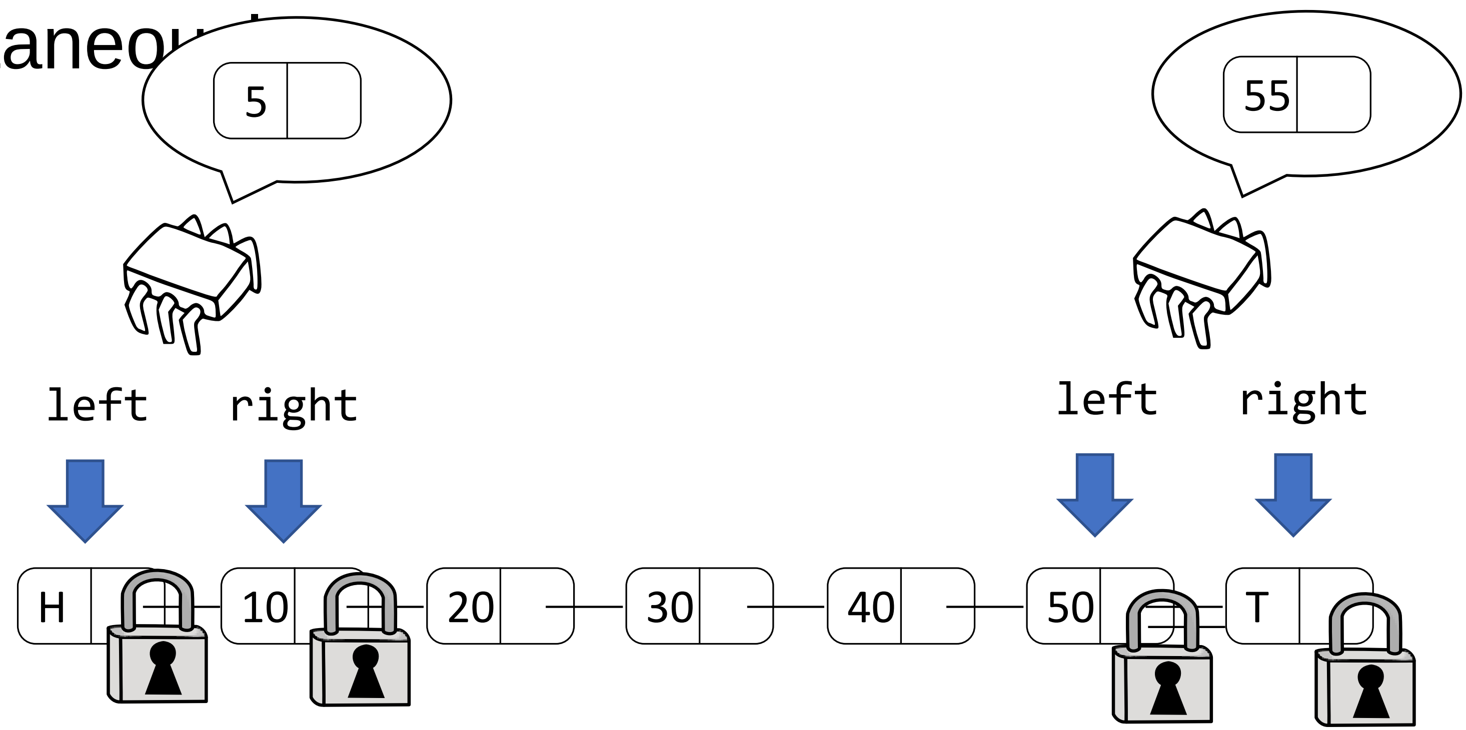
- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor

INSERT(55)



Search algorithm

- Keep two locks at a time (lock coupling):
  - One on the current node
  - One on its predecessor
- Multiple threads access the data structure simultaneou

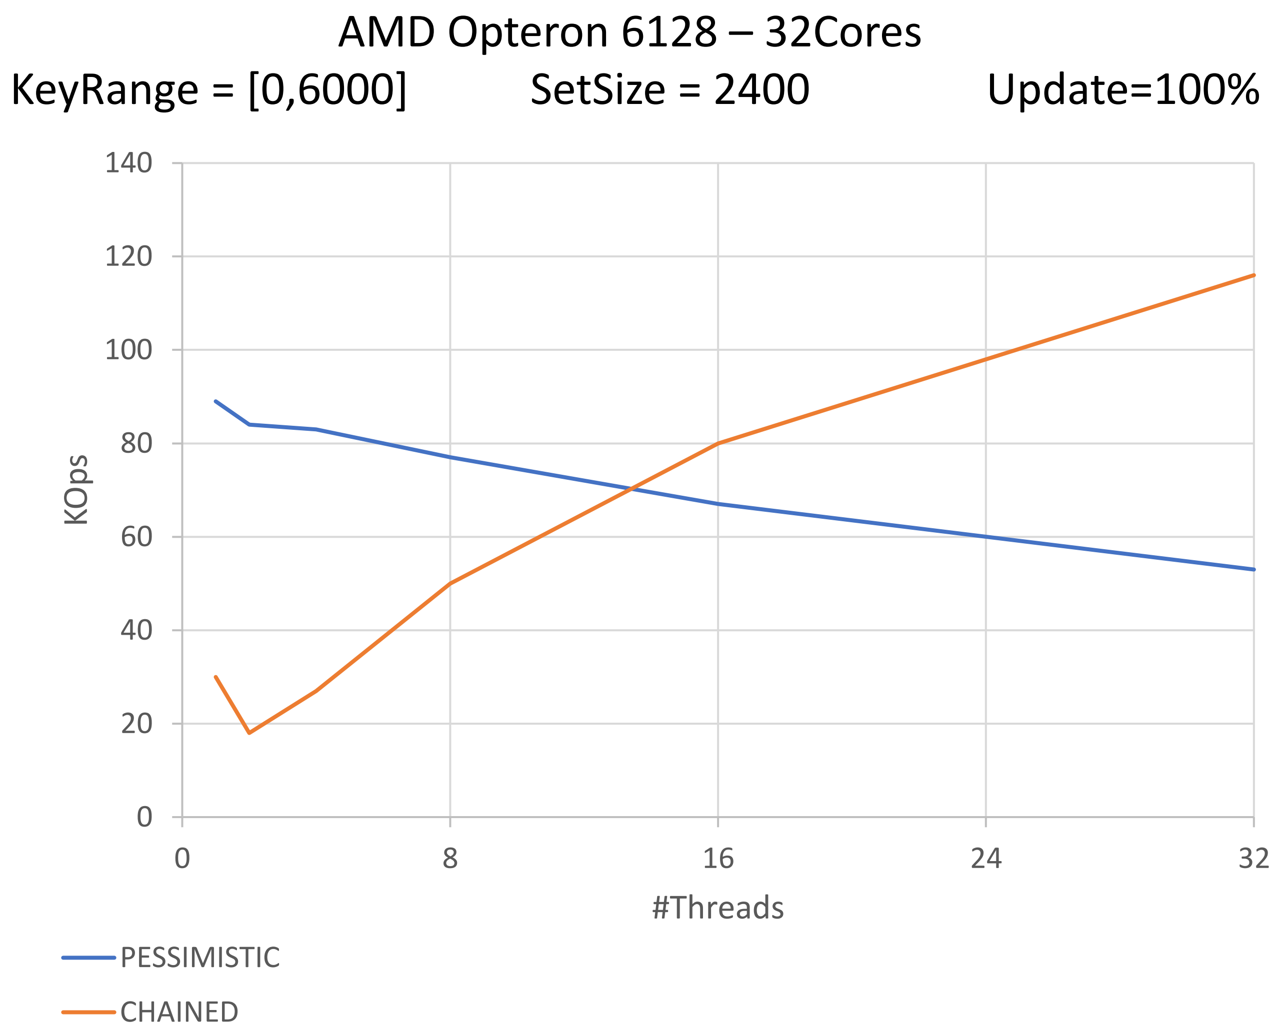


Concurrent set – Attempt 2 (SRC)

```
bool do_operation(int k, int op_type){
  bool res = true;
  node *l,*r;
  LOCK(&glock);
  l = search(k, &r);
  switch(op_type){
    case(INSERT):
      if(r->key == k)
        res = false;
      else
        l->next = new node(k,r);
      break;
    case(DELETE):
      if(r->key == k)
        l->next = r->next;
      else
        res = false;
      break;
  }
  UNLOCK(&glock);
  UNLOCK(&l->lock);
  UNLOCK(&r->lock);
  return res;
}
```

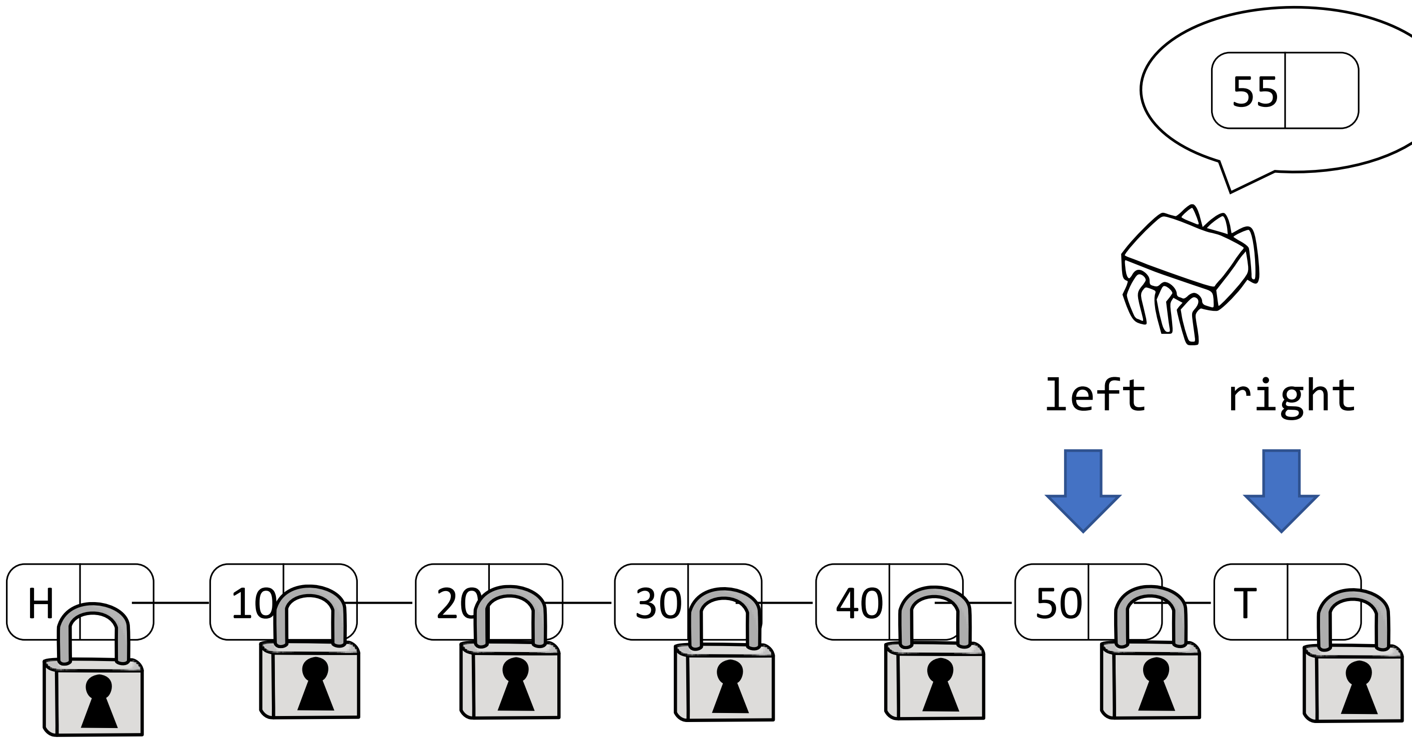
```
node* search(int k, node **r){
  node *l, *r_next;
  l = set->head;
  LOCK(&l->lock);
  *r = l->next;
  LOCK(&(*r)->lock);
  r_next = (*r)->next;
  while((*r)->key < k){
    UNLOCK(&l->lock);
    l = *r;
    *r = r_next;
    LOCK(&(*r)->lock);
    r_next = (*r)->next;
  }
}
```

Concurrent set – Attempt 2



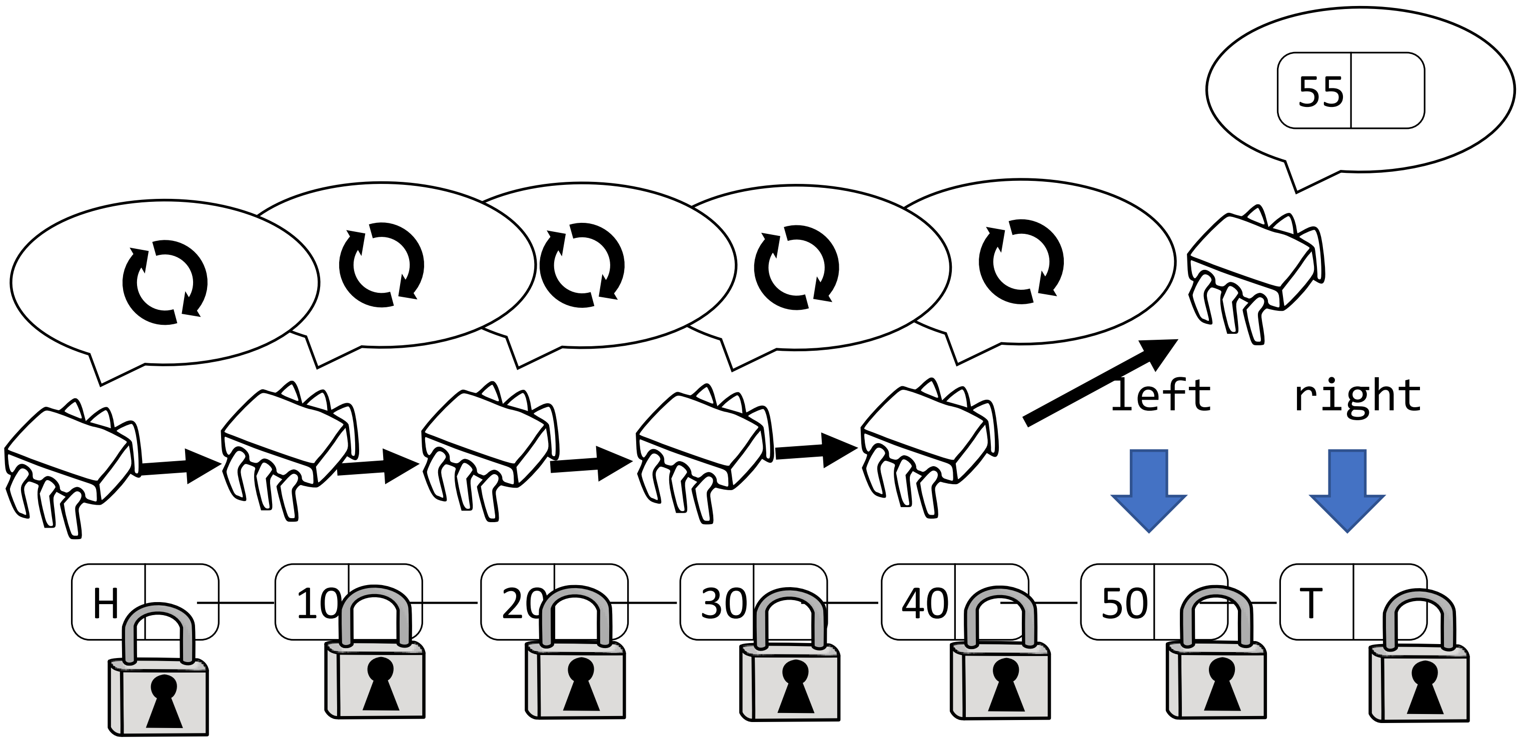
Search algorithm

- Allows an increased parallelism but…



Search algorithm

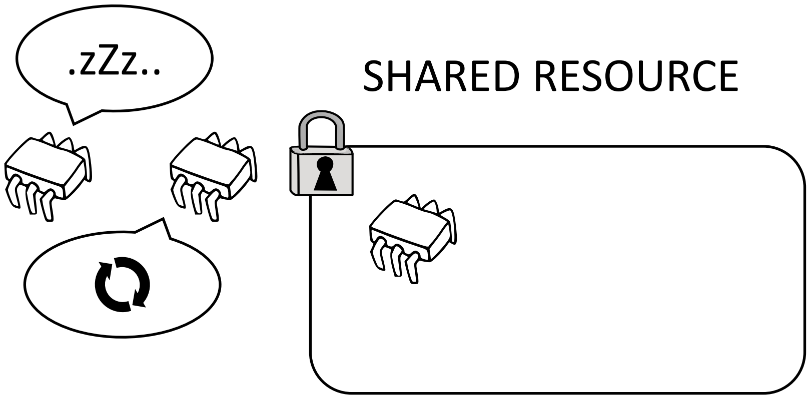
- Allows an increased parallelism but…
- High costs for lock handover



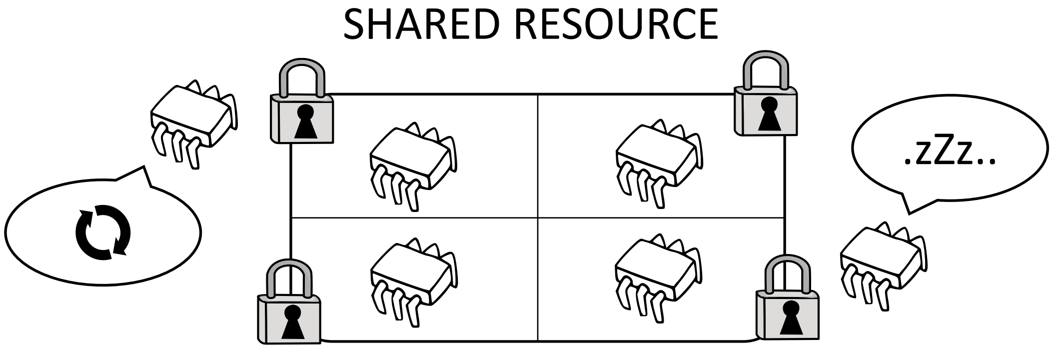
Recap

- Explored two blocking strategies:

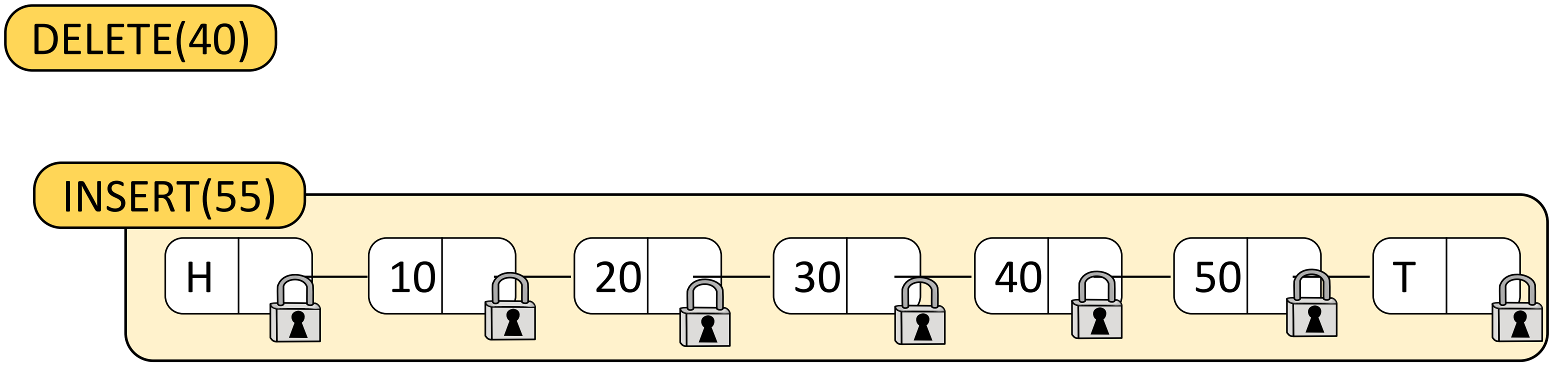
1. Global (coarse-grain) lock



2. (Fine-grain) Lock coupling

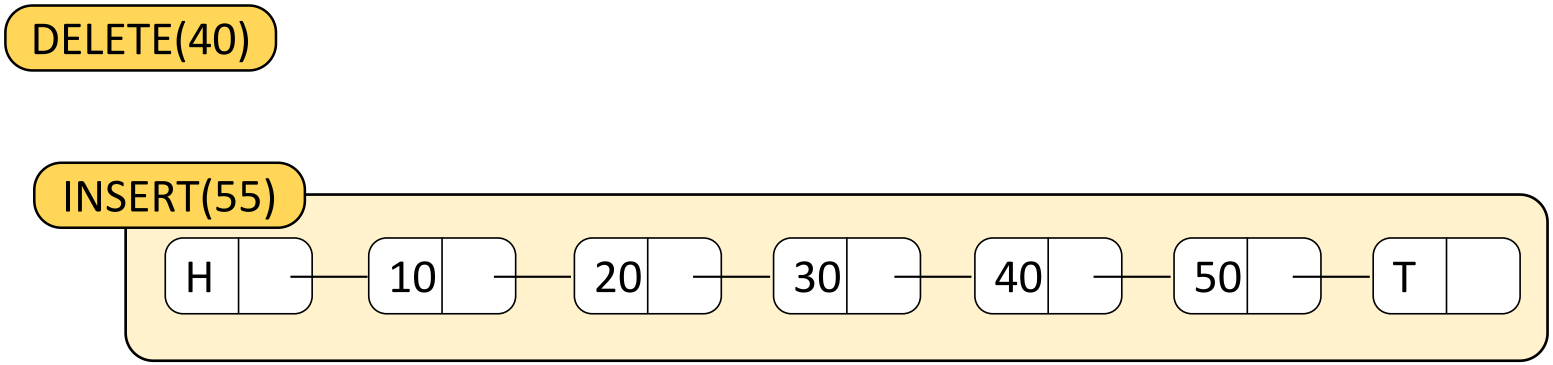


Concurrent set – Attempt 3



Concurrent set – Attempt 3

- NON-BLOCKING approach [Harris linked list]
- Search without acquiring any lock
- Apply updates with individual atomic instructions



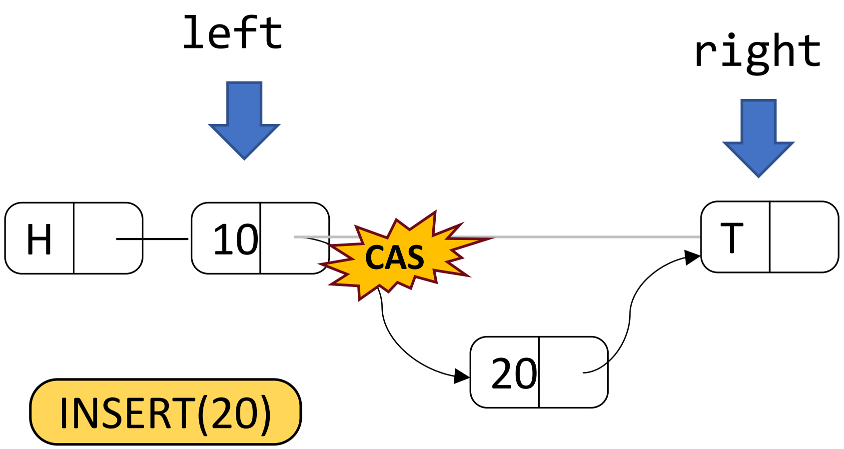
Non-blocking insert & delete algorithms

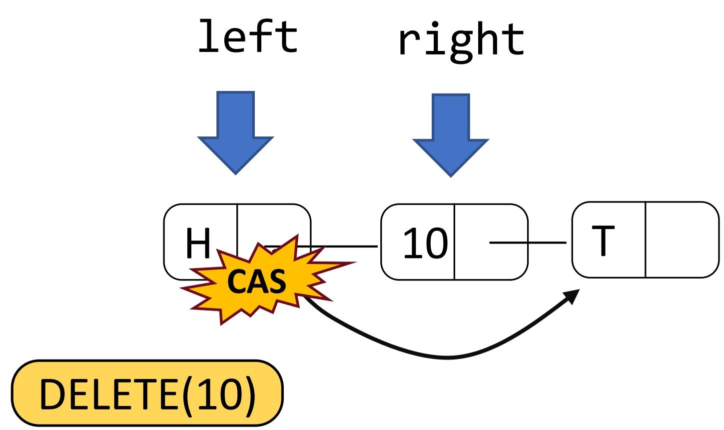
Insert:

1. Search left and right nodes
2. Insert the new item with a CAS
3. If CAS fails restart from 1

Delete:

1. Search left and right nodes
2. Disconnect the item with a CAS
3. If CAS fails restart from 1





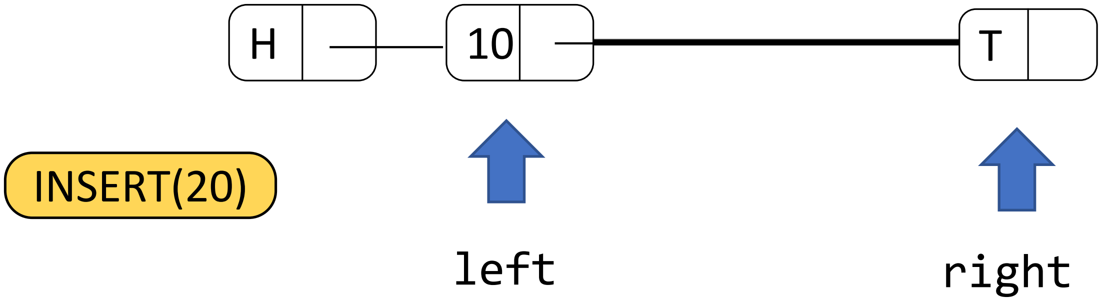
- Is it correct?

Incorrect delete algorithm

- Edge cases might lead to losing items!

Incorrect delete algorithm

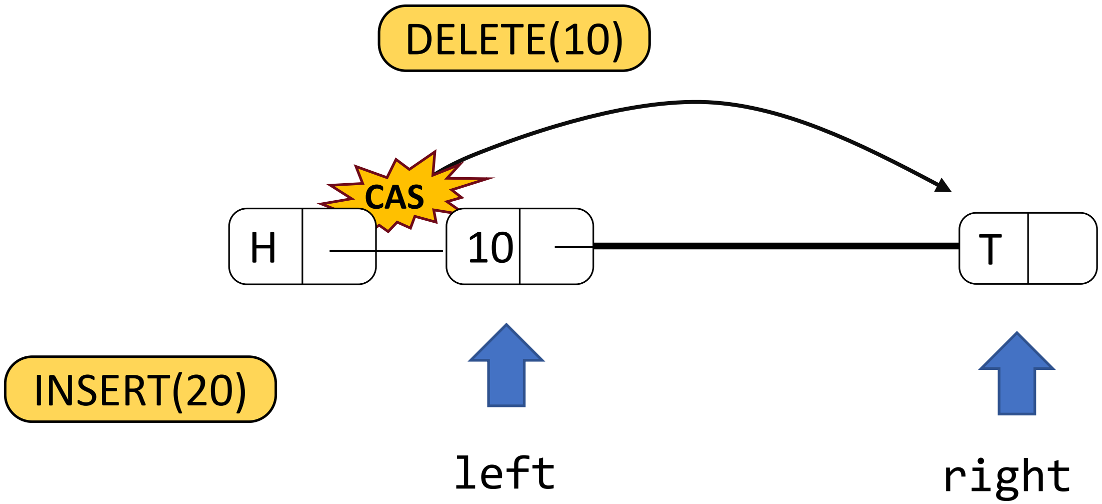
- Edge cases might lead to losing items!



1. Thread A gets left and right node and go to sleep
2. Thread B disconnects the node containing 10
3. Thread A wakes up and add 20 after 10
4. The new item is lost

Incorrect delete algorithm

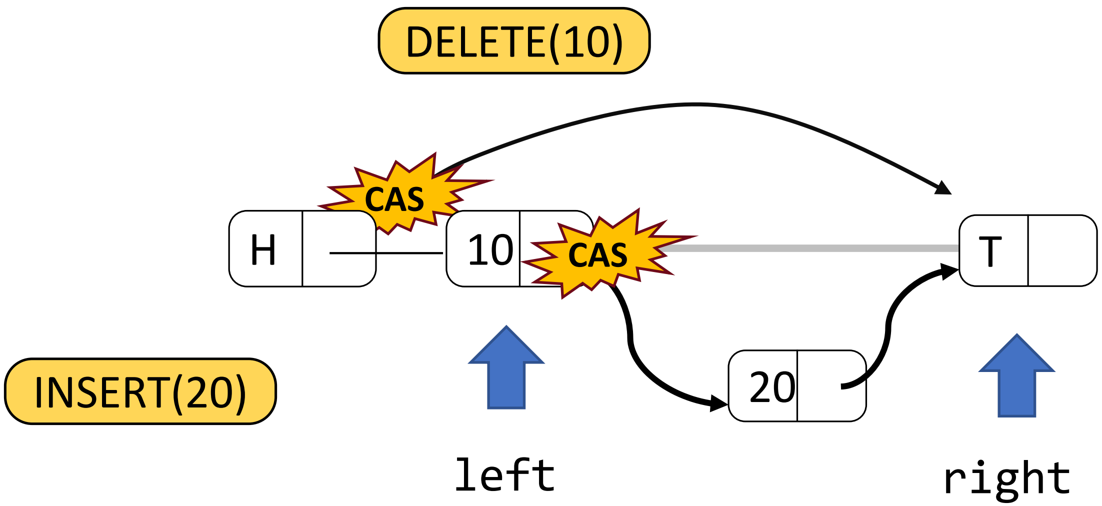
- Edge cases might lead to losing items!



1. Thread A gets left and right node and go to sleep
2. Thread B disconnects the node containing 10
3. Thread A wakes up and add 20 after 10
4. The new item is lost

Incorrect delete algorithm

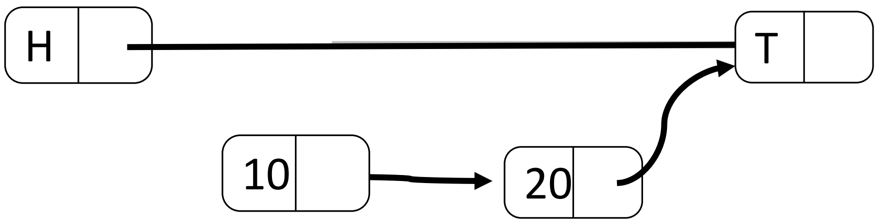
- Edge cases might lead to losing items!



1. Thread A gets left and right node and go to sleep
2. Thread B disconnects the node containing 10
3. Thread A wakes up and add 20 after 10
4. The new item is lost

Incorrect delete algorithm

- Edge cases might lead to losing items!

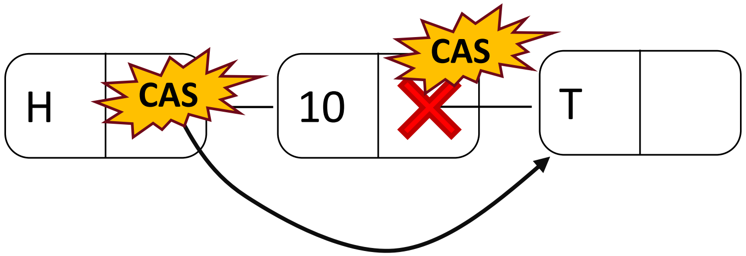


1. Thread A gets left and right node and go to sleep
2. Thread B disconnects the node containing 10
3. Thread A wakes up and add 20 after 10
4. The new item is lost

The correct delete algorithm

- Adopt logical deletion:

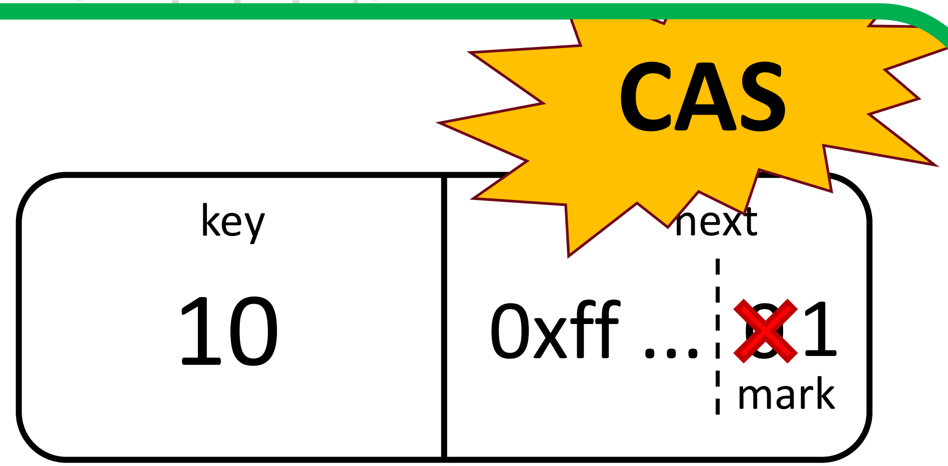
1. Get left and right node
2. Mark the item as deleted via CAS (*logical* deletion)
3. If CAS fails GOTO 1
4. Disconnect the item via CAS (*physical* deletion)
5. If CAS fails GOTO 4



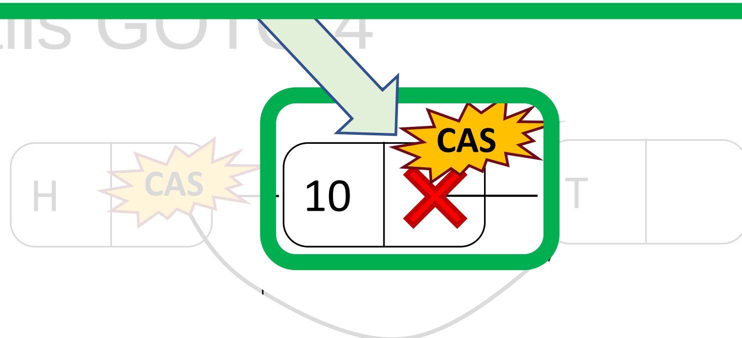
The correct delete algorithm

- Adopt

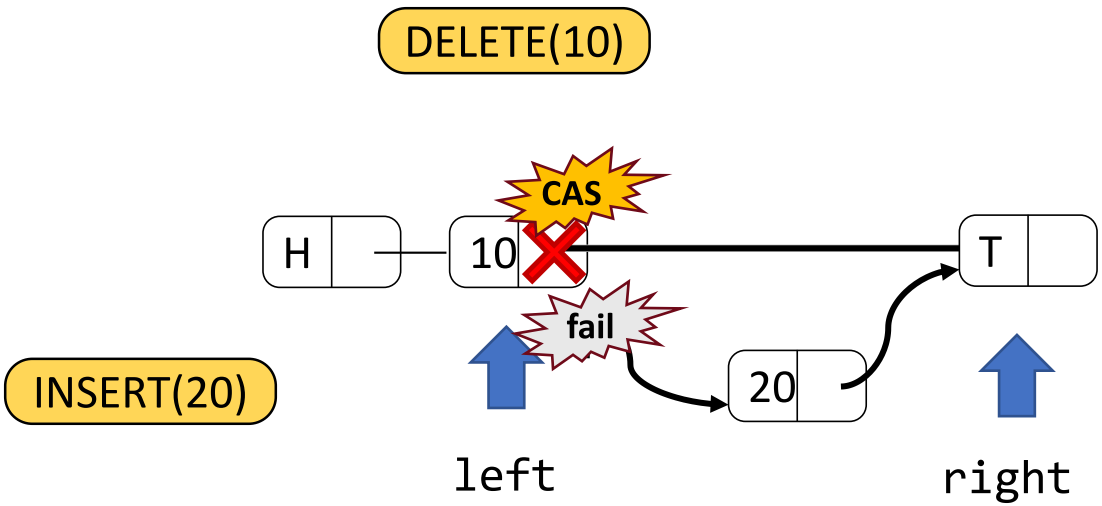
1. Ge
2. Ma ... ogical de
3. If C
4. Di ... cal deletion)
5. If CAS fails GOTO 4



- Typically memory objects are byte aligned
- The LSB is always 0! BIT STEALING!!!



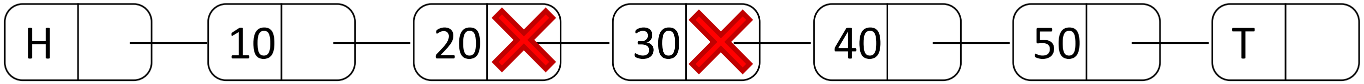
The correct delete algorithm



- Updates of the ”`next`” field by two opposite concurrent operations cannot both succeed
- What to do upon conflict (failed CAS)? RESTART FROM SCRATCH!!

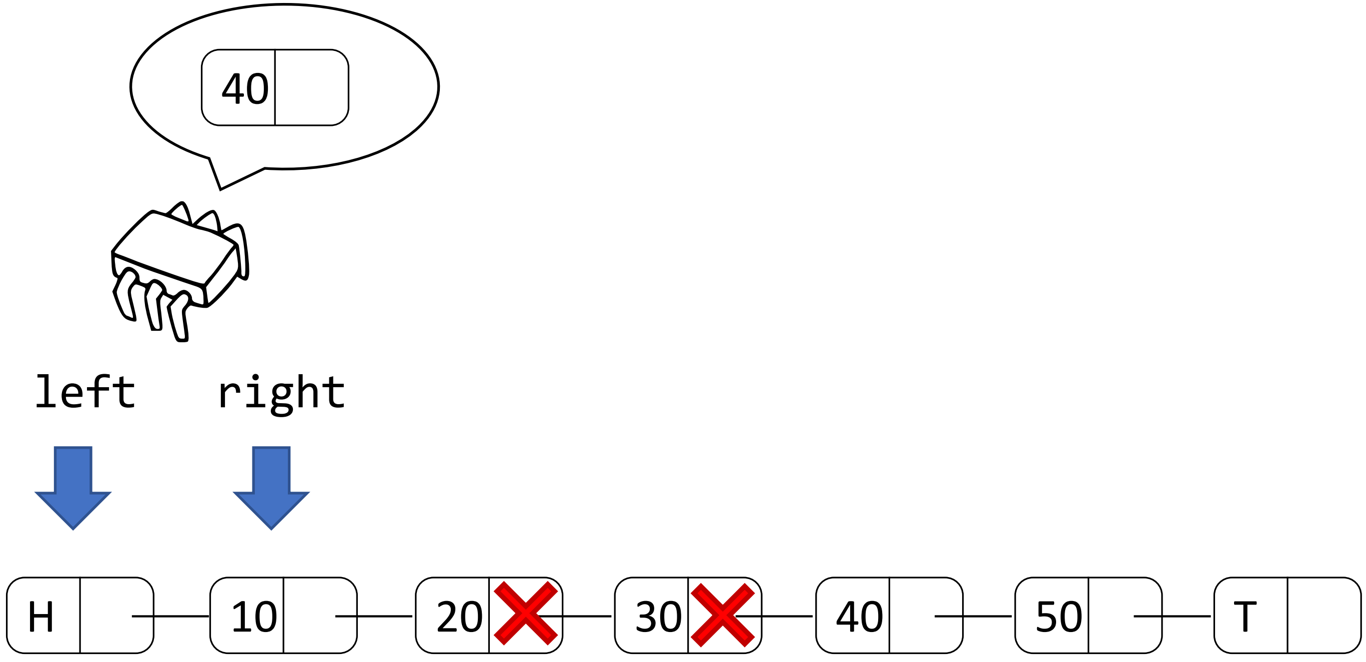
Non-blocking search

- The search returns two adjacent non-marked (left and right) nodes
- Housekeeping: disconnect logically delete items during searches



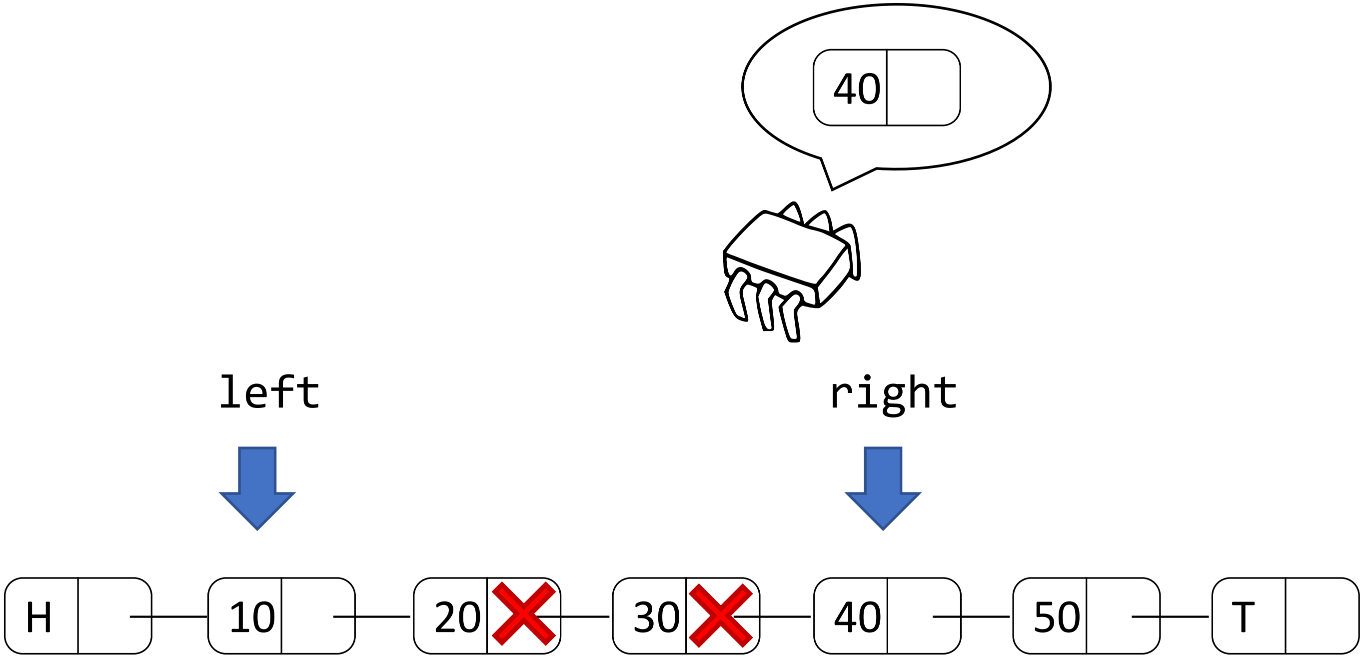
Non-blocking search

- The search returns two adjacent non-marked (left and right) nodes
- Housekeeping: disconnect logically delete items during searches



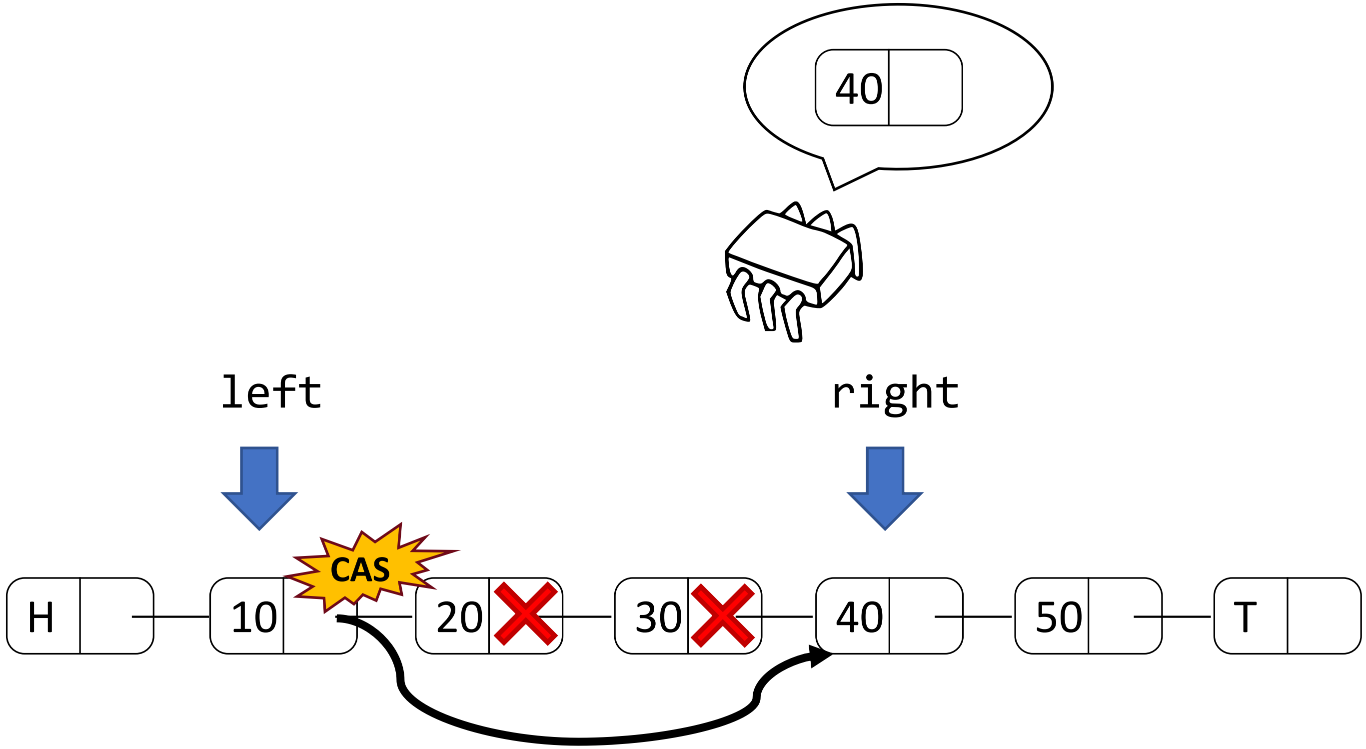
Non-blocking search

- The search returns two adjacent non-marked (left and right) nodes
- Housekeeping: disconnect logically delete items during searches



Non-blocking search

- The search returns two adjacent non-marked (left and right) nodes
- Housekeeping: disconnect logically delete items during searches



Concurrent set – Attempt 3 (SRC)

```
bool do_operation(int k, int op_type){
  node *l,*r, *n = new node(k);
  l = search(k, &r);                     /* get left and right node */
  switch(op_type){
    case(INSERT):
      if(r->key == k) return false;   /* key present in the set */
      n->next = r;
      l->next = n;                       /* insert the item        */
      break;
    case(DELETE):
      if(r->key != k) return false;   /* key not present        */
      l->next = r->next;                 /* remove the key         */
      break;
  }
  return true;
}
```

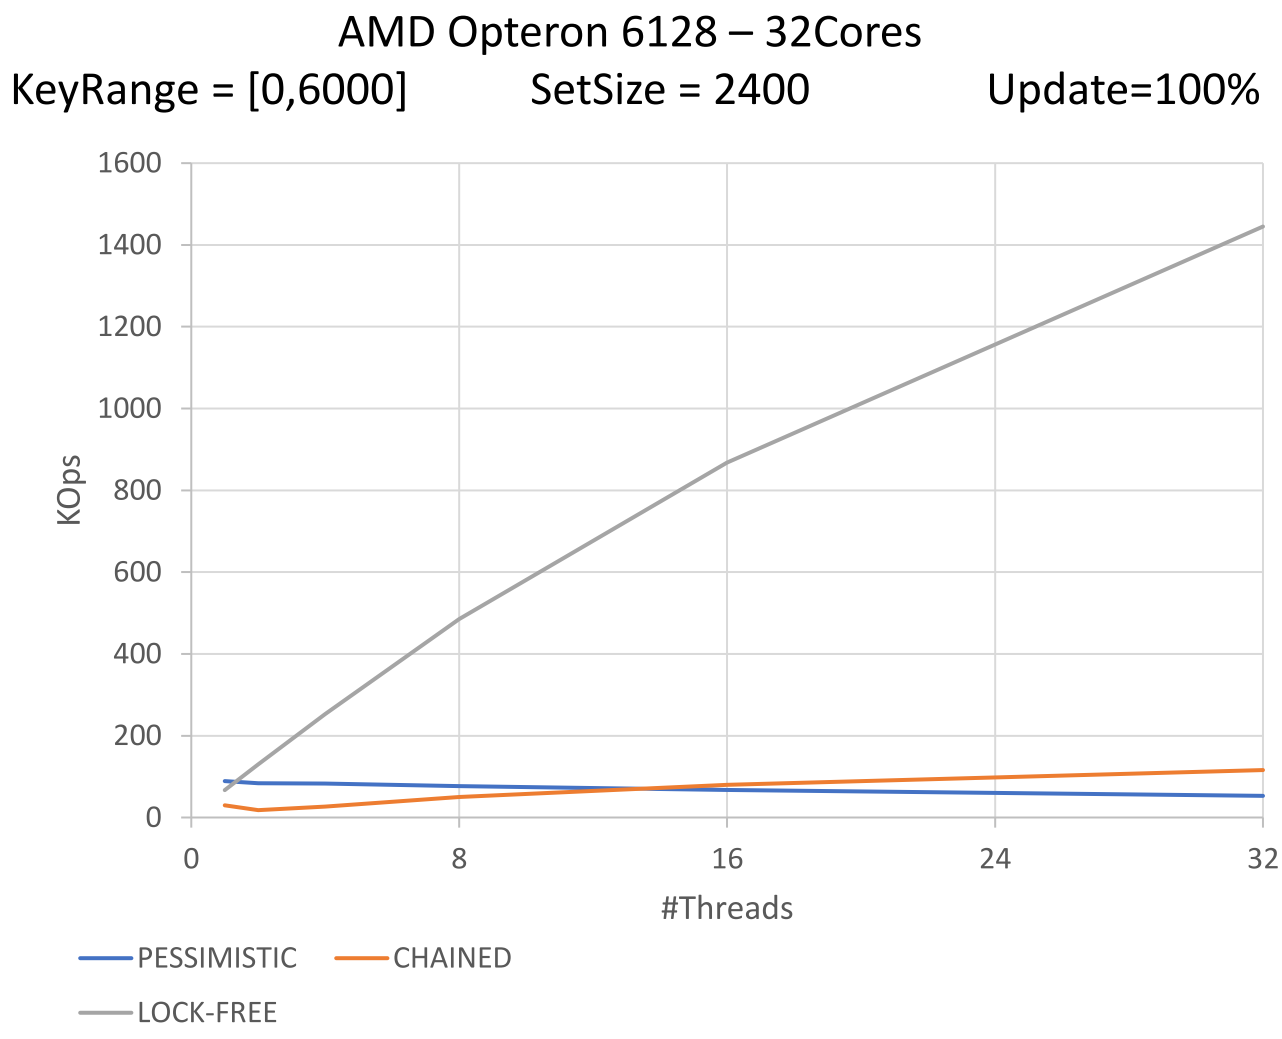
Concurrent set – Attempt 3 (SRC)

```
1. bool do_operation(int k, int op_type){
2.   node *l,*r, *n = new node(k);
3.   l = search(k, &r);                     /* get left and right node */
4.   switch(op_type){
5.     case(INSERT):
6.       if(r->key == k) return false;    /* key present in the set */
7.       n->next = r;
8.       l->next = n;                       /* insert the item        */
9.       if(!CAS(&l->next, r, n))
10.         goto 3;          /* insertion failed the item -> restart */
11.       break;
12.     case(DELETE):
13.       if(r->key != k) return false;    /* key not present        */
14.       l->next = r->next;                 /* remove the key         */
15.       if(is_marked_ref((l=r->next)) || !CAS(&r->next, l, mark(l)))
16.         goto 3;          /* insertion failed the item -> restart */
17.       search(k,&r);                      /* repeat search          */
18.       break;
19.   }
20.   return true;
21.}
```

Concurrent set – Attempt 3 (SRC)

```
node* search(int k, node **r){
  node *l, *t, *t_next, *l_next;
  *t = set->head;
   t_next = t->head->next;
   while(1){                          /* FIND LEFT AND RIGHT NODE */
      if(!is_marked(t_next)){
         l = t;
         l_next = t_next;
      }
     t = get_unmarked_ref((t_next);
     t_next = t->next;
     if(!is_marked_ref(t_next) && t->key >= k) break;
  }
  *r = t;
  /* DEL MARKED NODES */
  if(l_next != *r && !CAS(&l->next, l_next, *r) goto 3;
  return l;
}
```

Concurrent set – Attempt 3



Safety and liveness guarantees

- The algorithm is NON-BLOCKING (LOCK-FREE):
  - If a thread A is stuck in a retry loop => a CAS fails each time
  - If a CAS fail, it is because of another CAS that was successfully executed by a thread B
  - Thread B is making progress
- The algorithm is LINEARIZABLE:
  - Each method execution take effect in an atomic point (a successful CAS) contained between its invocation and reply
  - The order obtained by using these points has been proved to be compliant with the Set semantic

Progress (Lock freedom)

- Each method update method has two main steps
  - A search, which might end with a CAS
  - A CAS to insert delete a node

1. Suppose an update method is stuck in a search:
   - The key range is finite, so the number of node is finite
   - It continuously fails to disconnect marked nodes
   - It means that new nodes have been both inserted and marked!
     - Other threads have completed update methods
2. Suppose an updated method always fails its last step (insertion or marking)
   - Other threads have modified the target next pointer
   - If it is due to the disconnection of marked nodes, see point 1
   - If it is due to the updated step other methods have completed

Safety (Linearizability)

1. The search returns 2 adjacent nodes in an atomic point
    1. The read of next field of the left node
    2. The CAS that make left and right adjacent

- It is like that the search made a snapshot of interested key interval

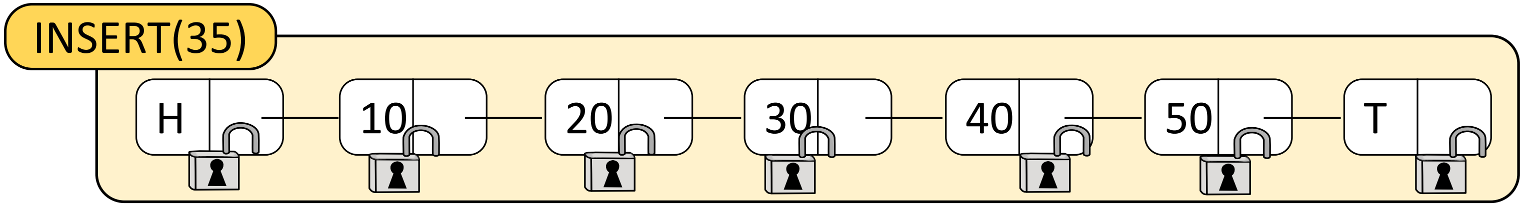
2. Find, unsuccessful delete and unsuccessful insert linearize with the search (1.1 or 1.2)
3. Insert linearizes with the successful CAS to connect a new node
4. Delete linearizes with the successful CAS to mark a node

Problems

- It is not possible to flip a bit of a reference on memory-managed languages (e.g. JAVA)
- How to solve?

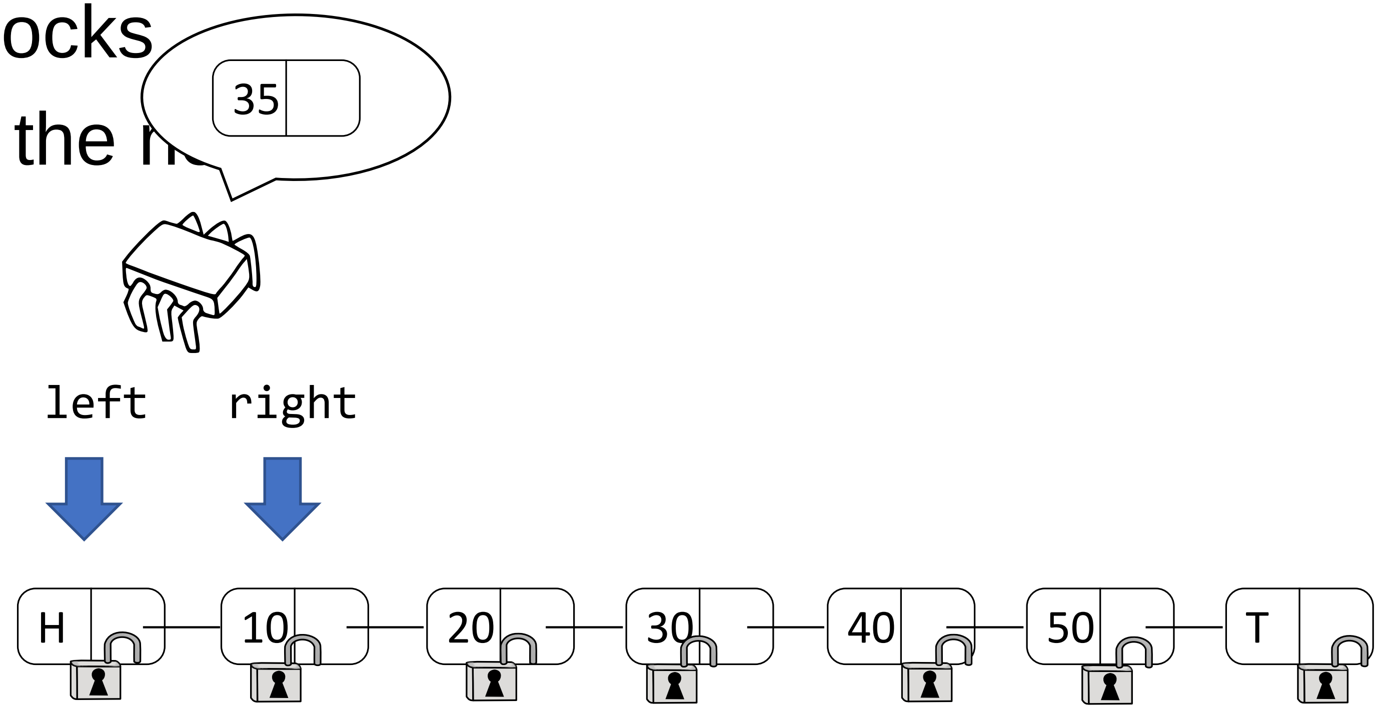
Locks + Optimism

- Use one lock per node
- Move “marked” to a dedicated field



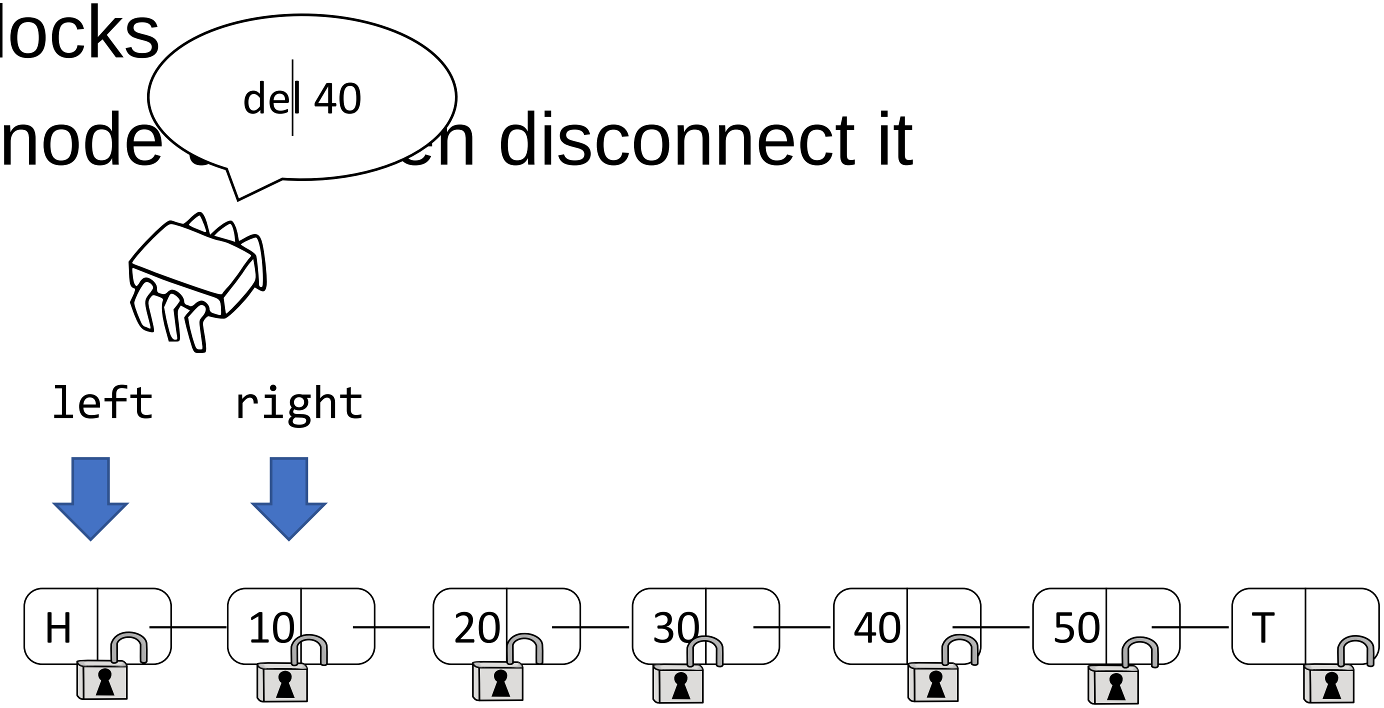
Locks + Optimism (insert)

- Use one lock per node
- Move “marked” to a dedicated field
- Find left and right without taking locks!
- Take locks
- Insert the n…



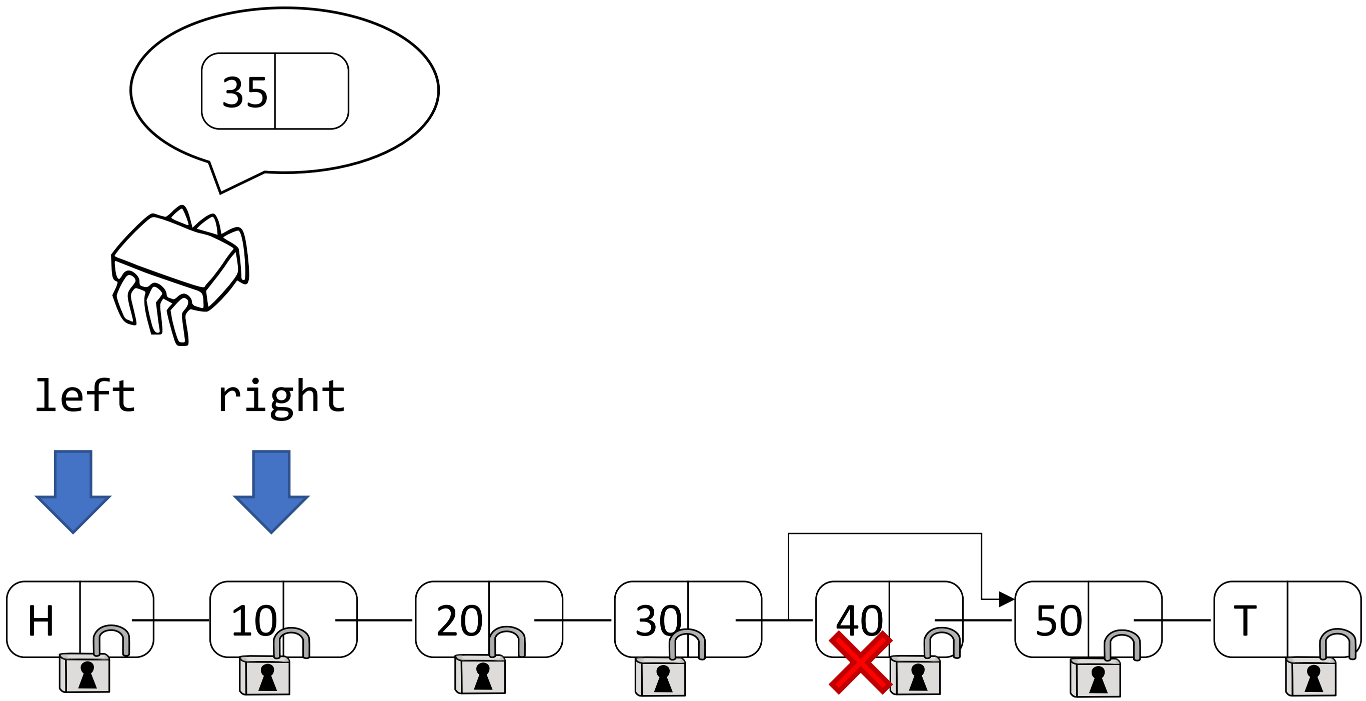
Locks + Optimism (delete)

- Use one lock per node
- Move “marked” to a dedicated field
- Find left and right without taking locks!
- Take locks
- Mark node … n disconnect it



Locks + Optimism (delete)

- Why "optimistic"? Do work (search) and hope nothing wrong happens!
- What could go wrong?



Locks + Optimism (delete)

- Why "optimistic"? Do work (search) and hope nothing wrong happens!
- What could go wrong?
  - Left and/or right being marked
  - Left and right not adjacent
- How to solve?
- Validation of search results:
  - Left unmarked
  - Right unmarked
  - Left.next = right

Locks + Optimism (delete)

- Why “optimistic”? Do work (search) and hope nothing wrong happens!
- What could go wrong?
  - Left and/or right being marked
  - Left and right not adjacent
- How to solve?
- Validation of search results:
  - Left unmarked
  - Right unmarked
  - Left.next = right

Locks + Optimism = Lazy List

- What about correctness?
- What about progress?

Can we do better?

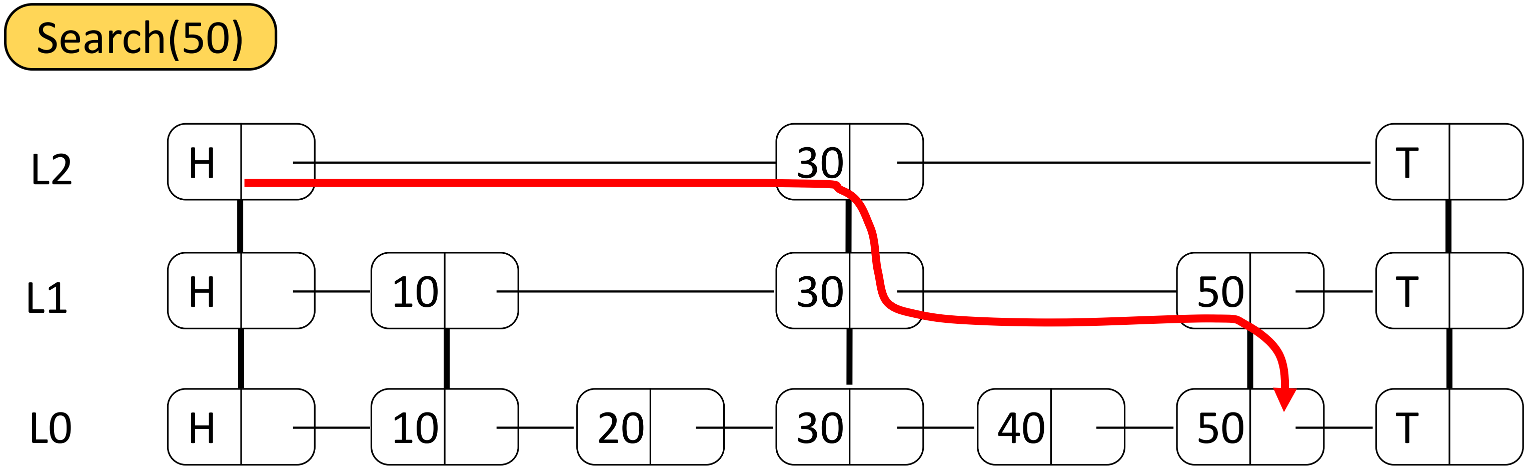
- Costs: O(n)
- Starting from scalable “simple” set implementation we can build faster set implementations
  - Hash table: O(1)
    - Array of buckets
    - Buckets are concurrent ordered-list based sets
- We know that a search in an ordered set could be more efficient O(log(n))
- How?

Skip list [Pugh 1990]

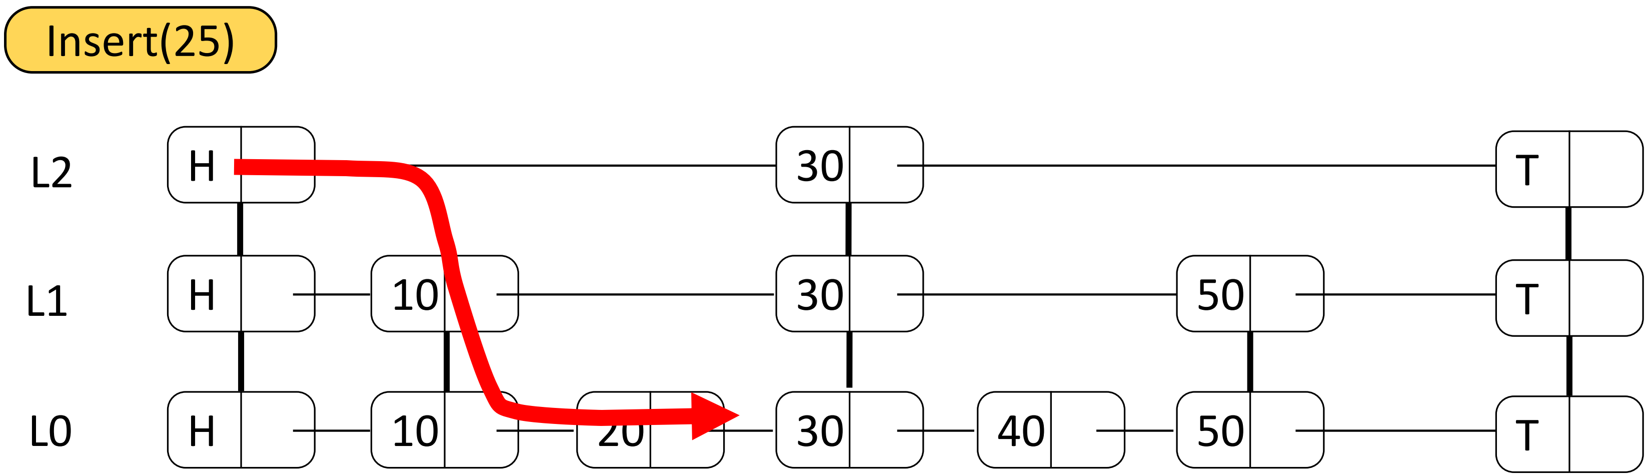
- Generalization of sorted linked lists
- Randomized data structure
- Costs: O(log(n))

- Idea:
  1. Maintain a core sorted linked list L0
  2. Use additional sorted linked lists Li such that:
     1. Li ⊂ Li-1
     2. |Li| ≈ |Li-1|/2
  3. Searches use lists in decreasing order

Skip list [Pugh 1990]

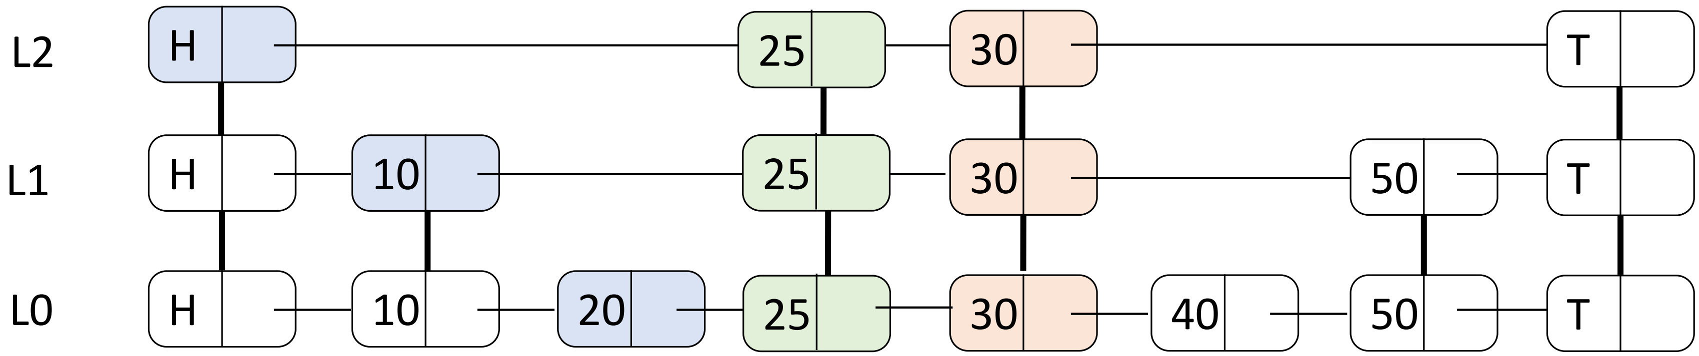


Skip list [Pugh 1990]



Skip list [Pugh 1990]

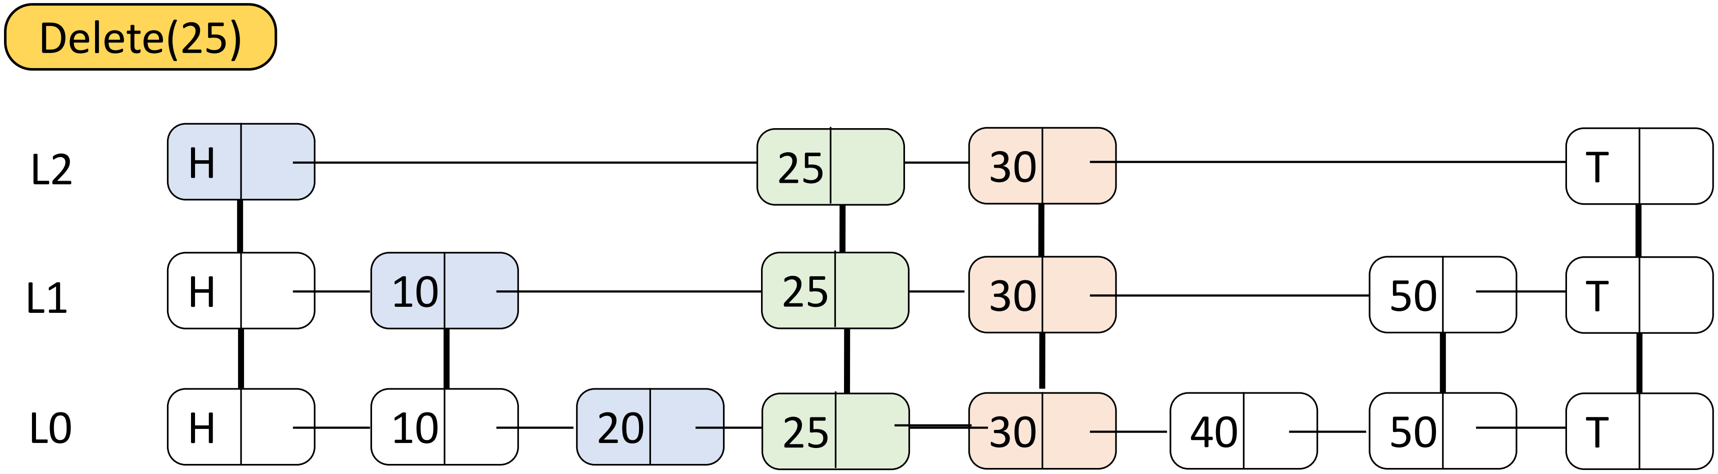
Insert(25)



Should I insert 25 at L1? Flip a coin!

Should I insert 25 at L2? Flip a coin!

Skip list [Pugh 1990]



Skip list [Pugh 1990]

- How many (expected) keys for each level?
- L0 = N
- L1 = N/2
- L2 = N/4

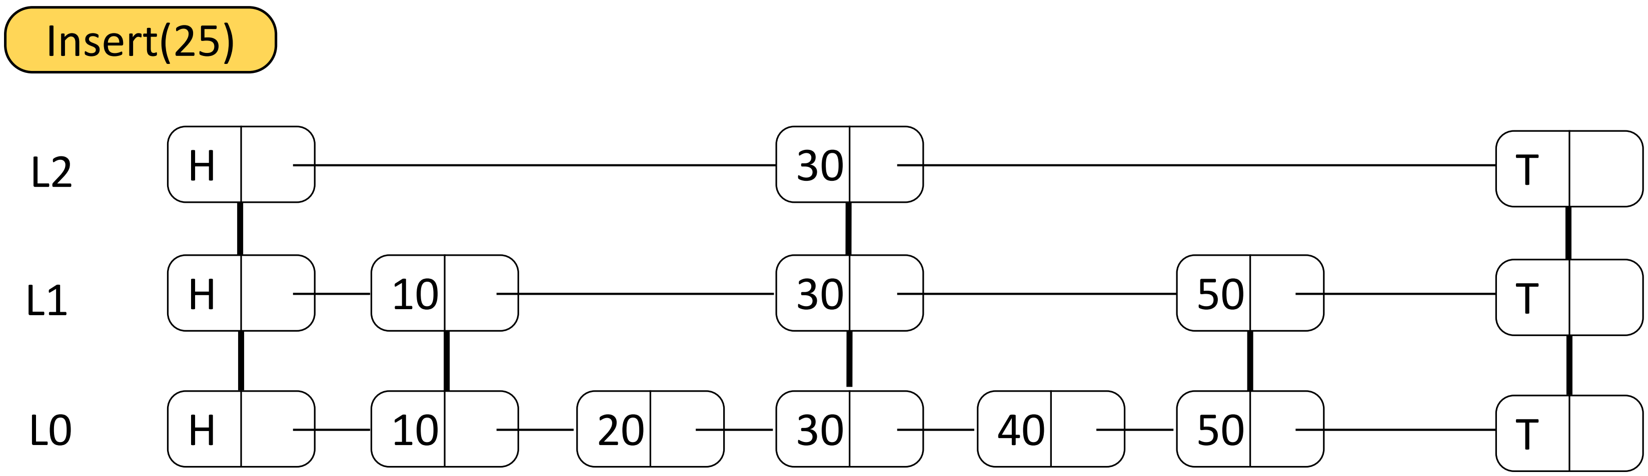
…

- L(logN) = 1

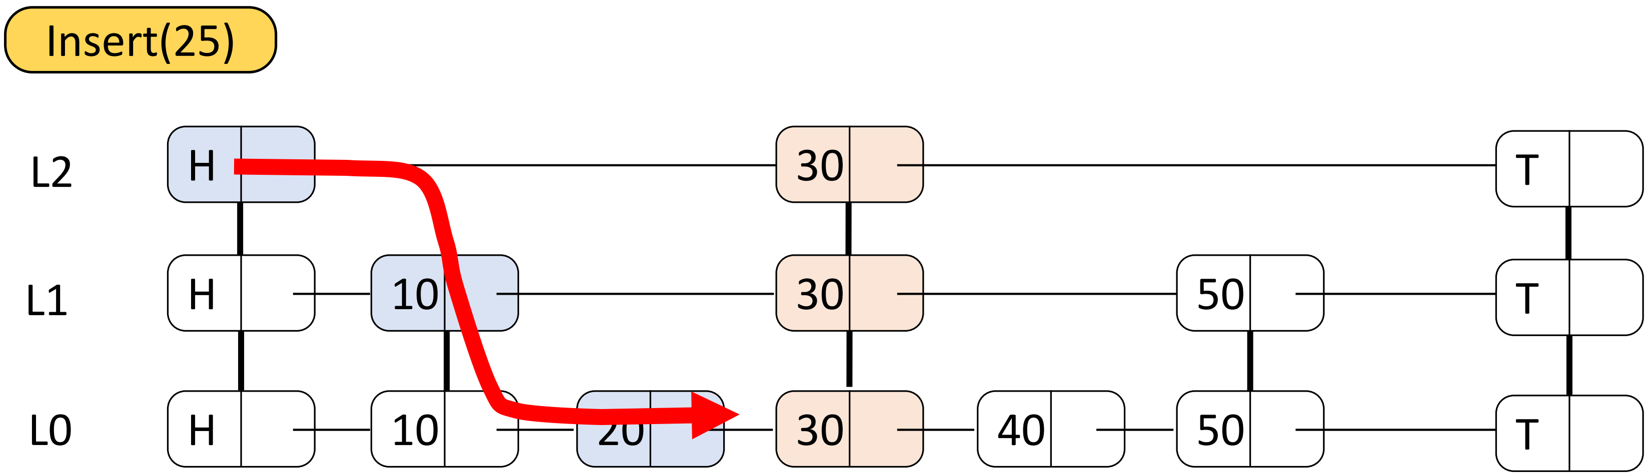
Skip list [Pugh 1990]

- How many steps per level?

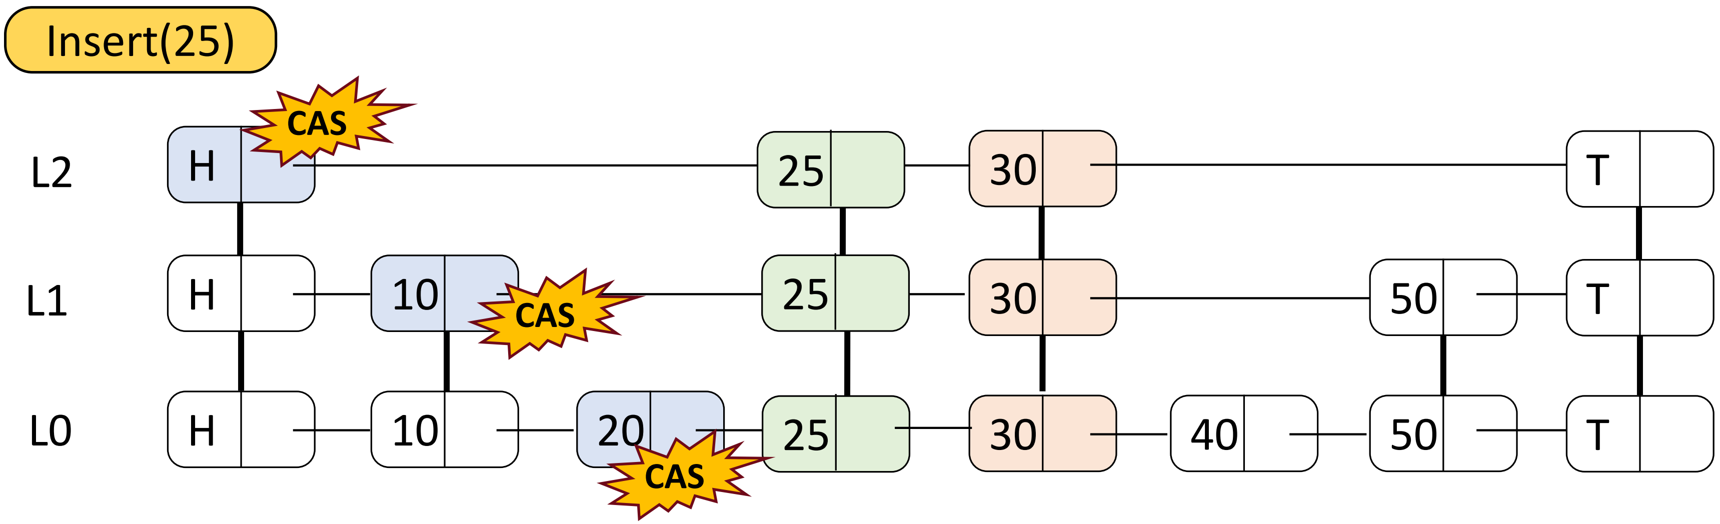
Non-blocking Skip list [Fraser2004]



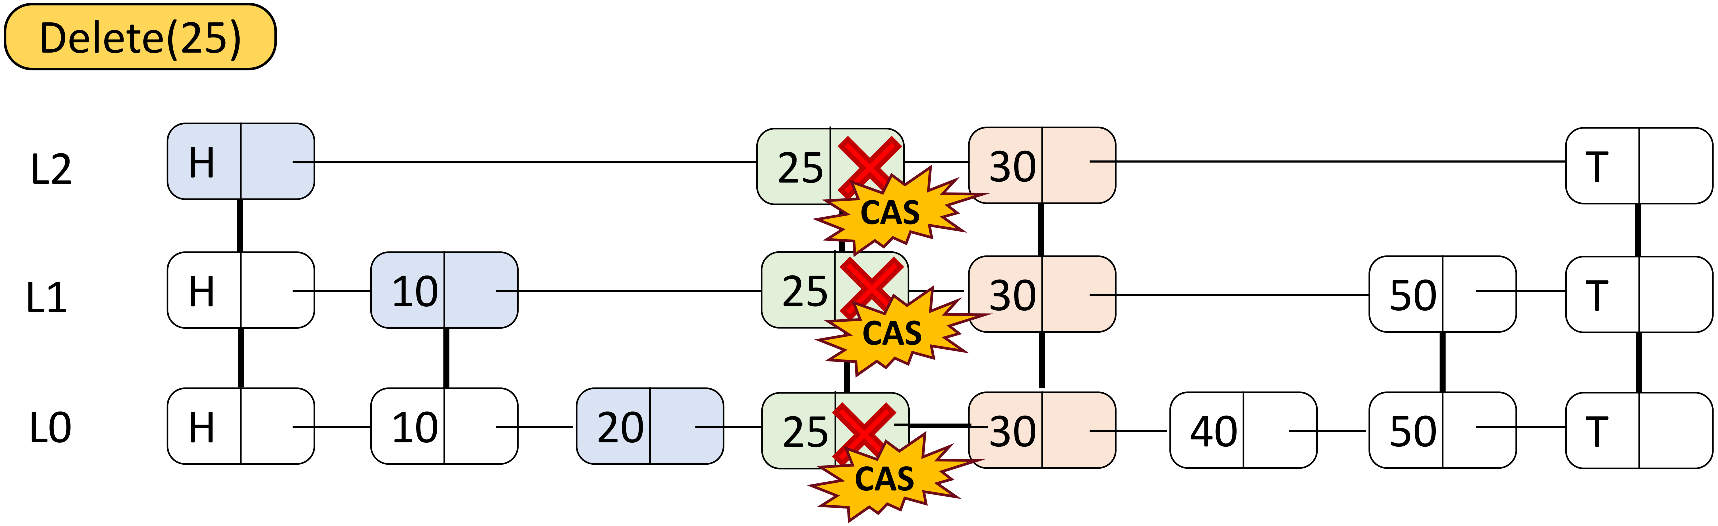
Non-blocking Skip list [Fraser2004]



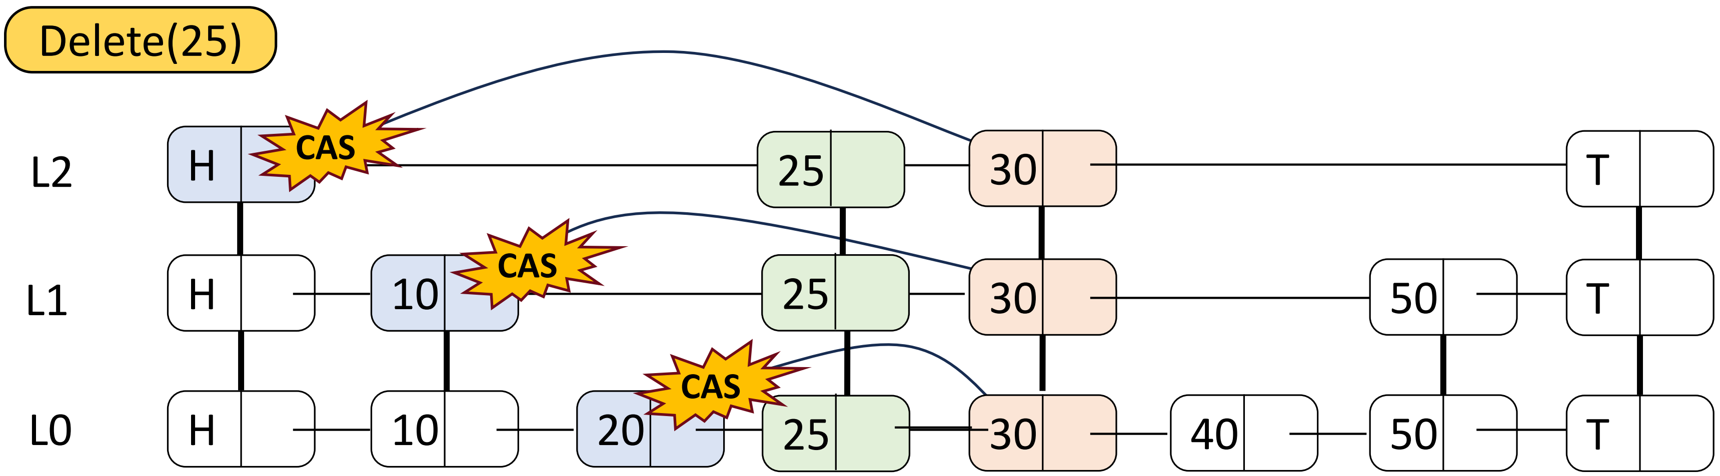
Non-blocking Skip list [Fraser2004]



Non-blocking Skip list [Fraser2004]



Non-blocking Skip list [Fraser2004]

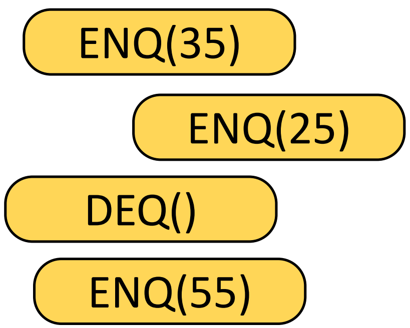


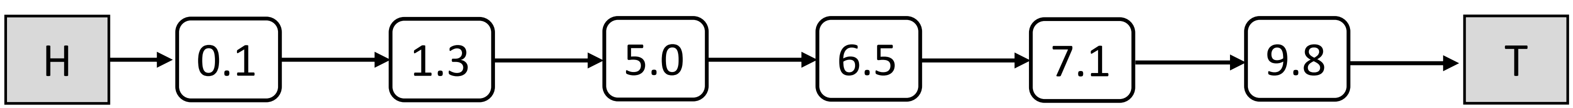
Concurrent Data Structures: Priority queues

Priority queue implementations

- Priority Queue methods:
  - `enqueue(k):` adds a new item
  - `dequeue():` returns and remove the highest priority item
- Implemented as an ordered linked list

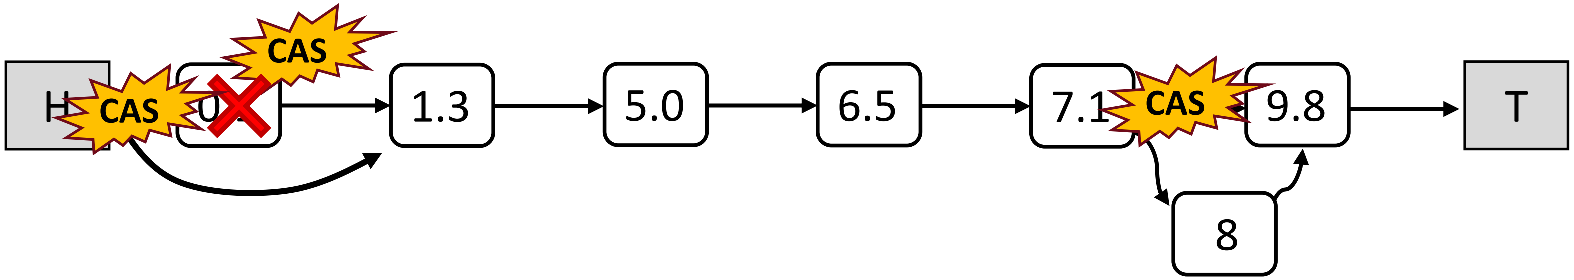
This is a huge simplification. Tipically they are implemented as skip-lists (log(n)) or calendar queues (O(1))



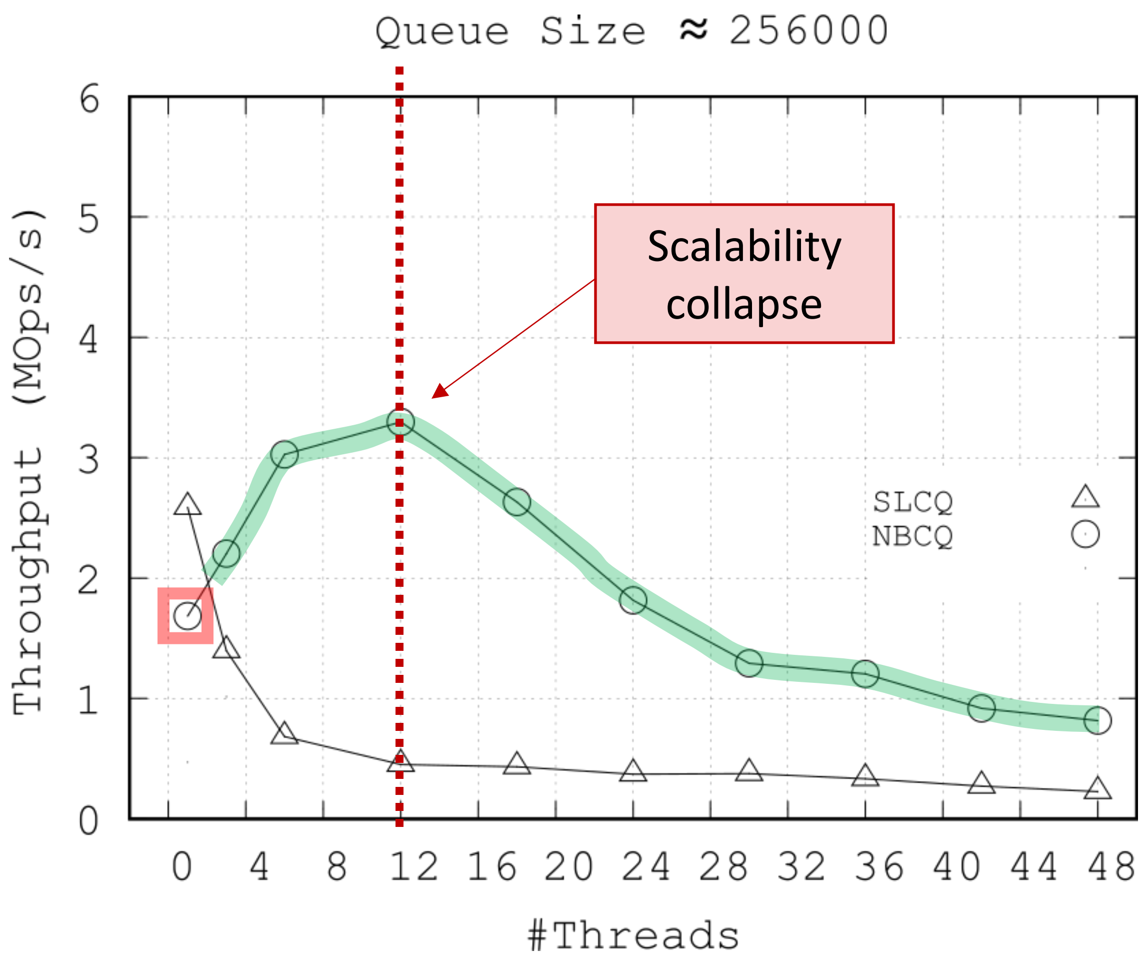


Priority queue – Attempt 1

- Enqueue: works as insertions in the non-blocking Set
  - Connect via CAS
- Dequeues: work as deletions in the non-blocking Set
  - Mark as logically deleted, but
  - DISCONNECT IMMEDIATELY
- Is it scalable?

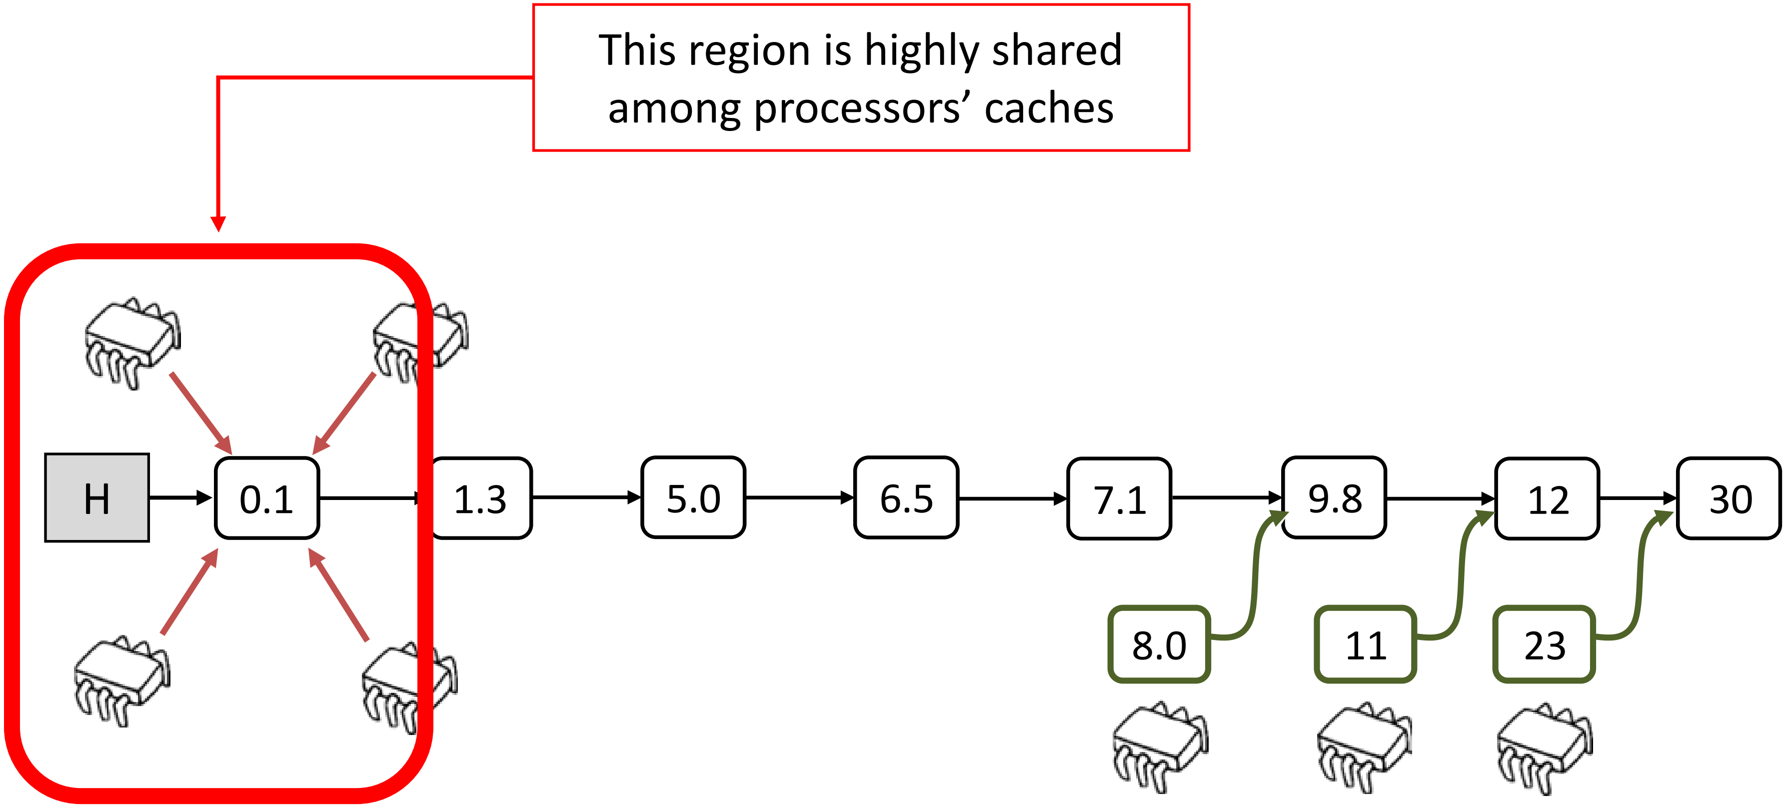


Priority queue – Attempt 1



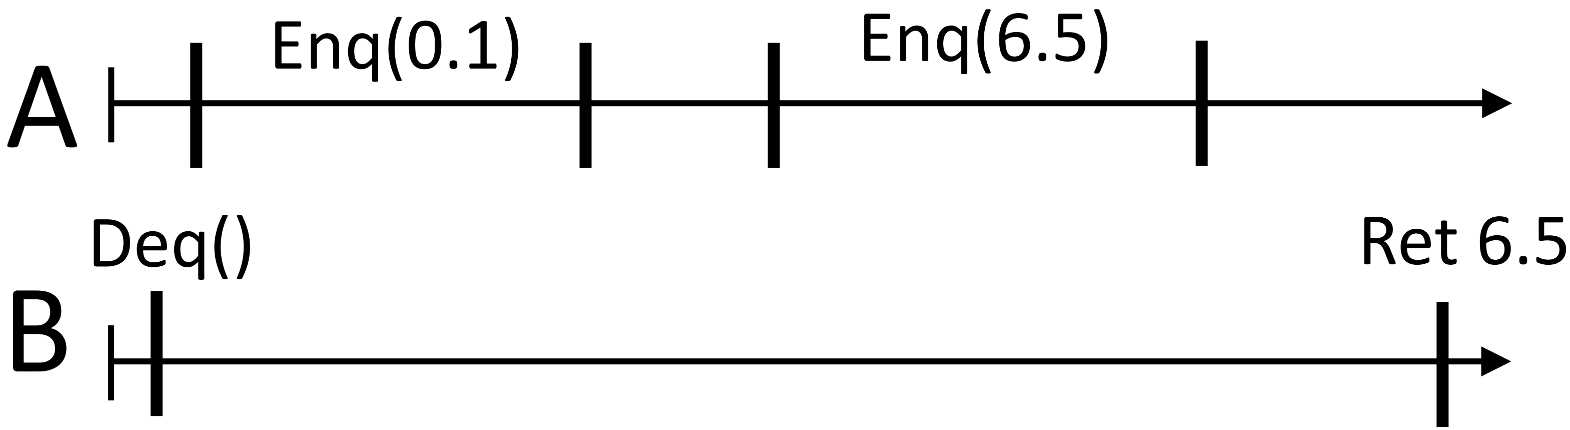
Priority queues: an inherently “sequential” semantic

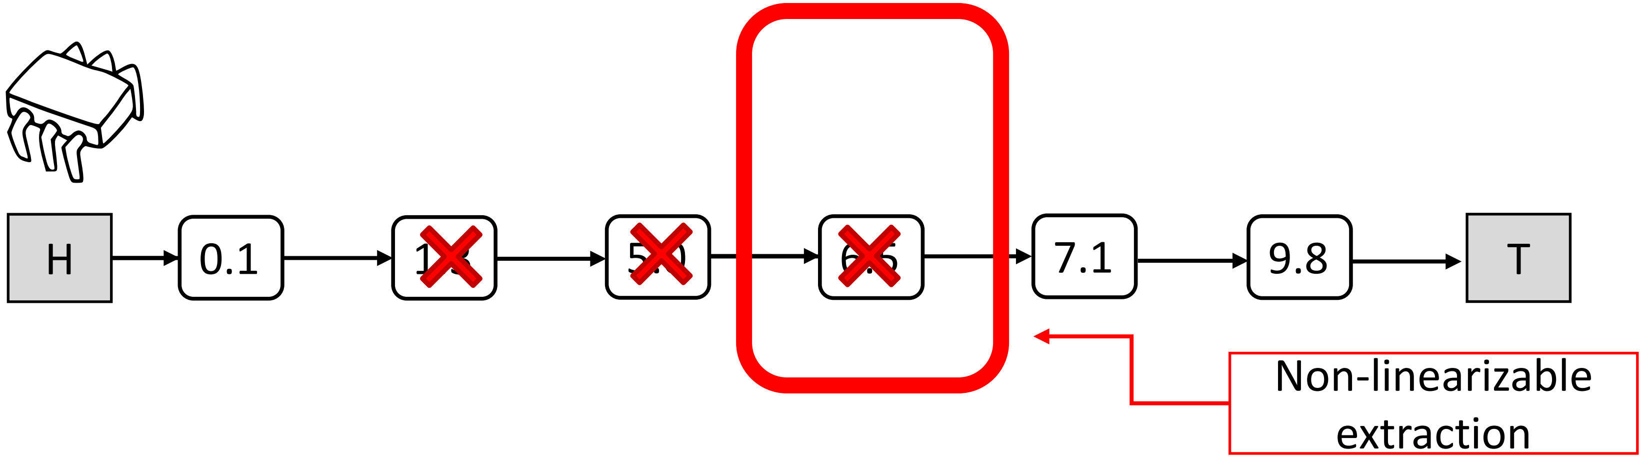
- Enqueue offers a high level of disjoint access parallelism
- Dequeues are prone to conflicts



Lazy deletion within priority queues

- If we use lazy deletion "as is", we might obtain non-linearizable extractions

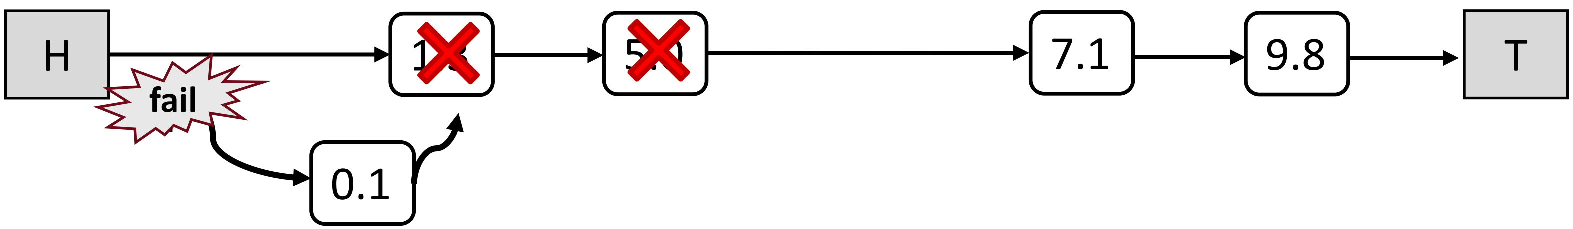




Correct lazy deletion within priority queues

- To implement correct extractions with lazy deletions there are two main approaches

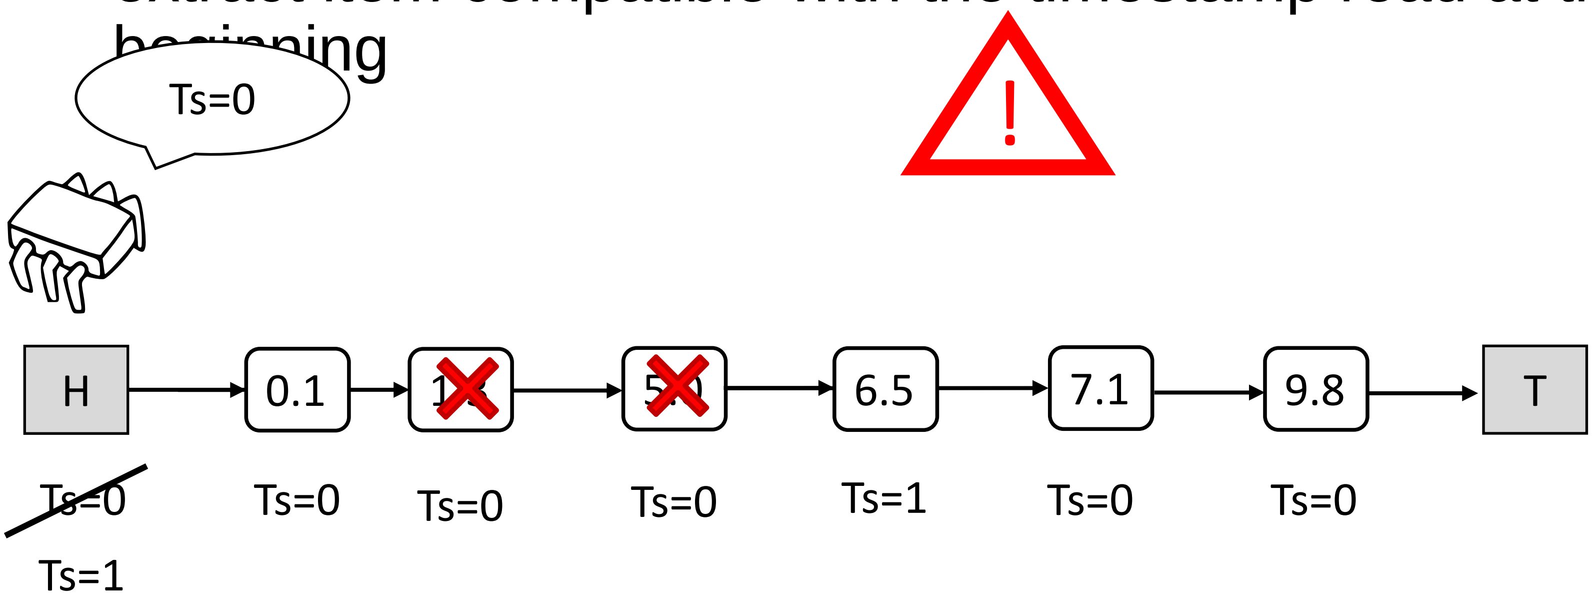
1. Move the logical mark of a node in the field "`next`" of its predecessor



Correct lazy deletion within priority queues

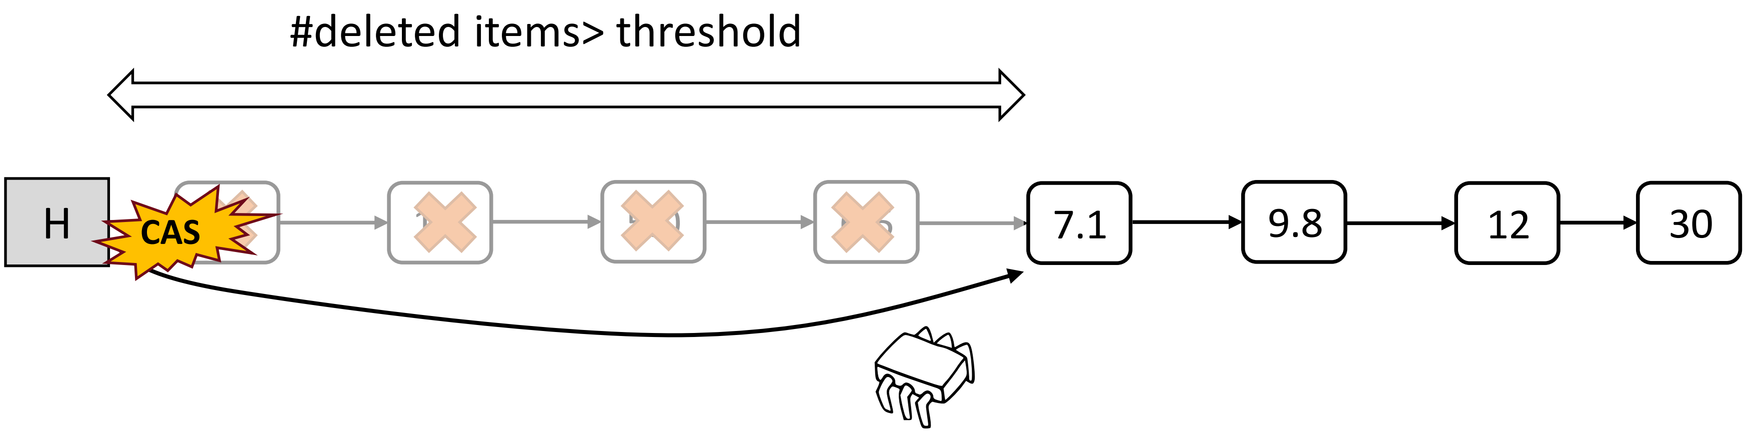
- To implement correct extractions with lazy deletions there are two main approaches

2. Use logical timestamps:
   - incremented each time a new minimum has been inserted
   - extract item compatible with the timestamp read at the beginning

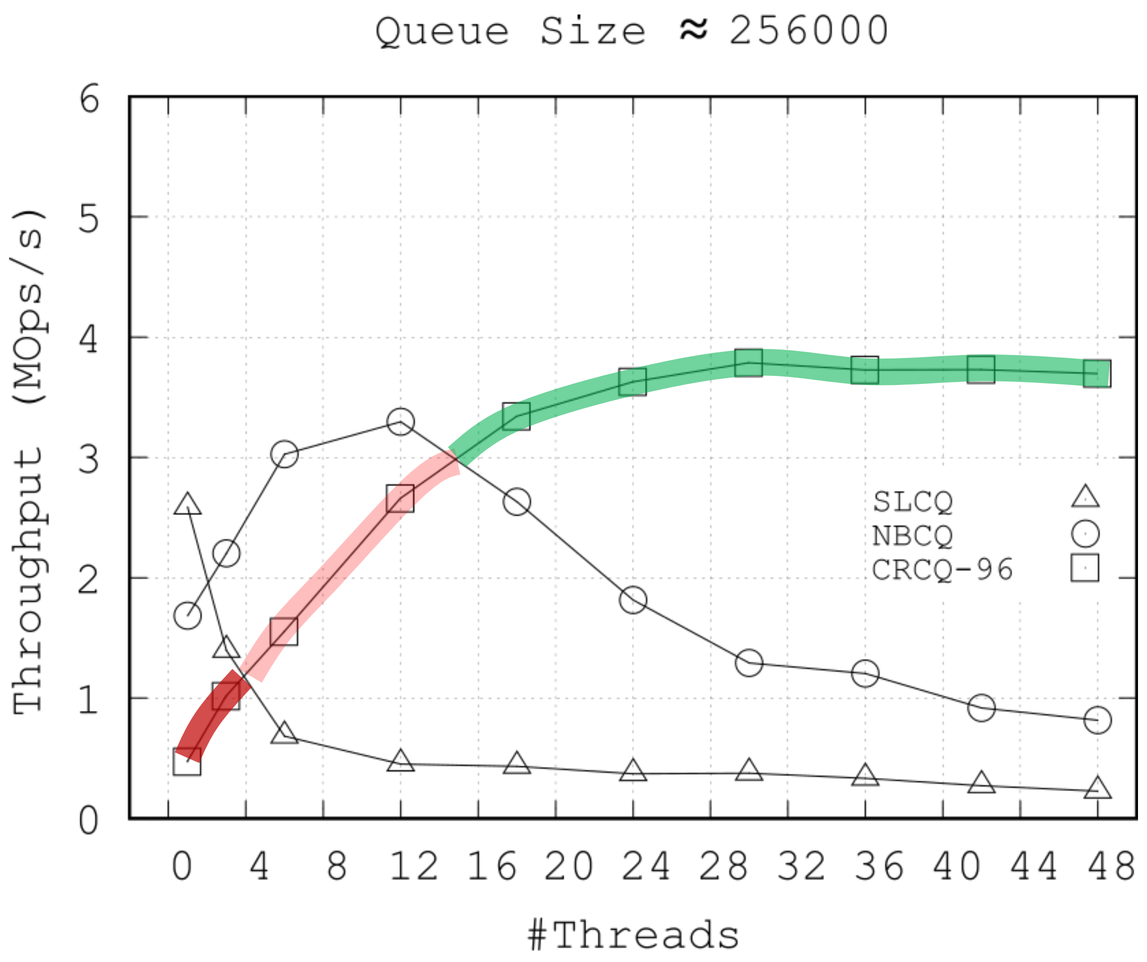


PQ – Attempt 2 - Introducing Conflict Resiliency

- Lazy deletion
- Skip logically deleted items $\Rightarrow$ IT INCREASES THE NUMBER OF STEPS $\Rightarrow$ EXPENSIVE IN TERMS OF IMPACT ON CACHE
- Periodic Housekeeping



Priority queue – Attempt 2



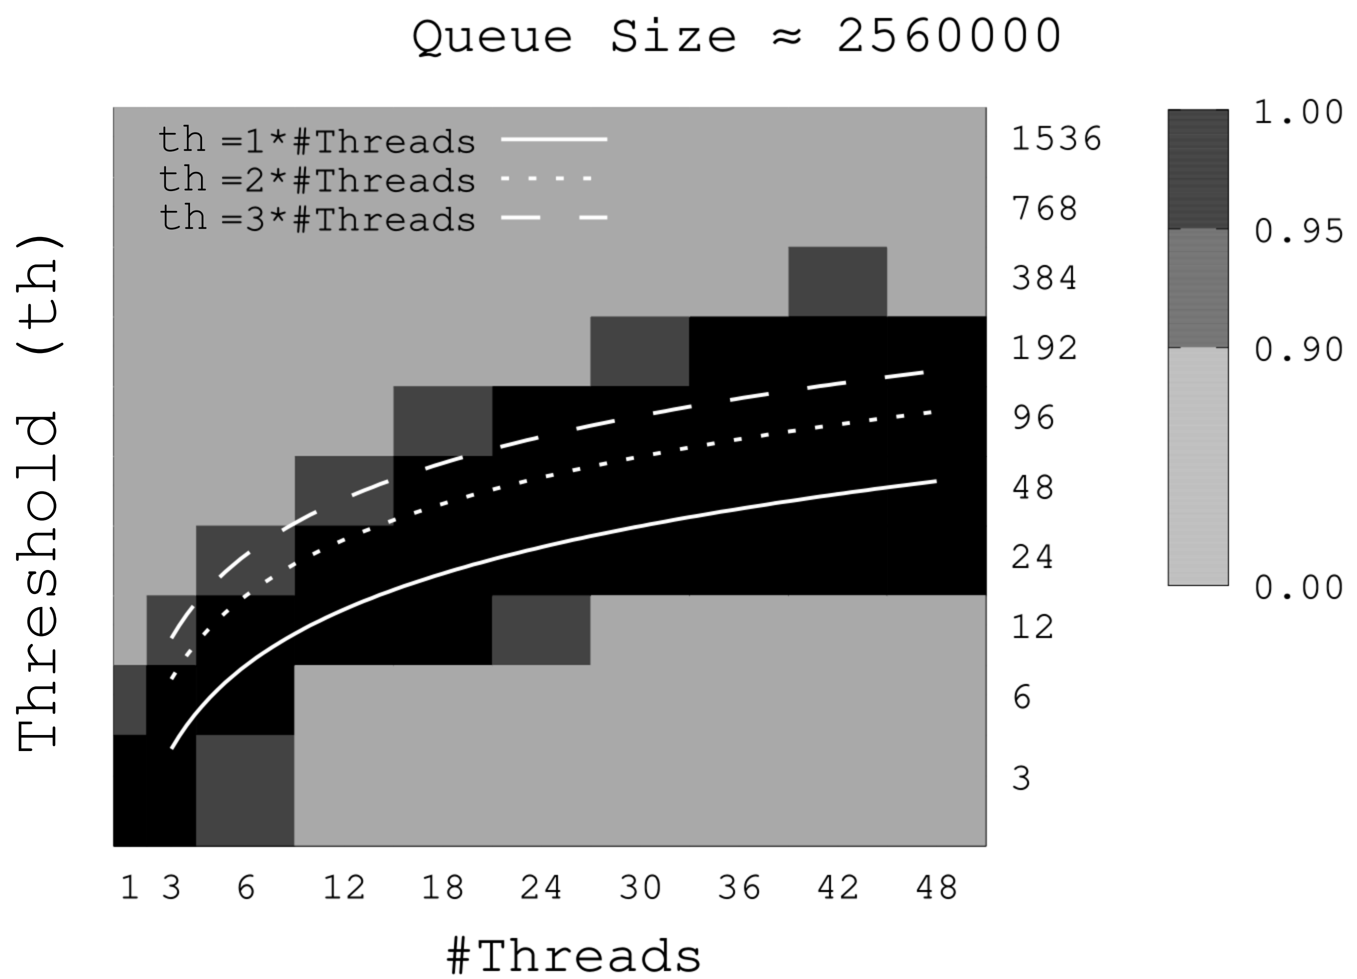
On the conflict resiliency trade off

- The number of steps per dequeue and costs of housekeeping are **dependent**:

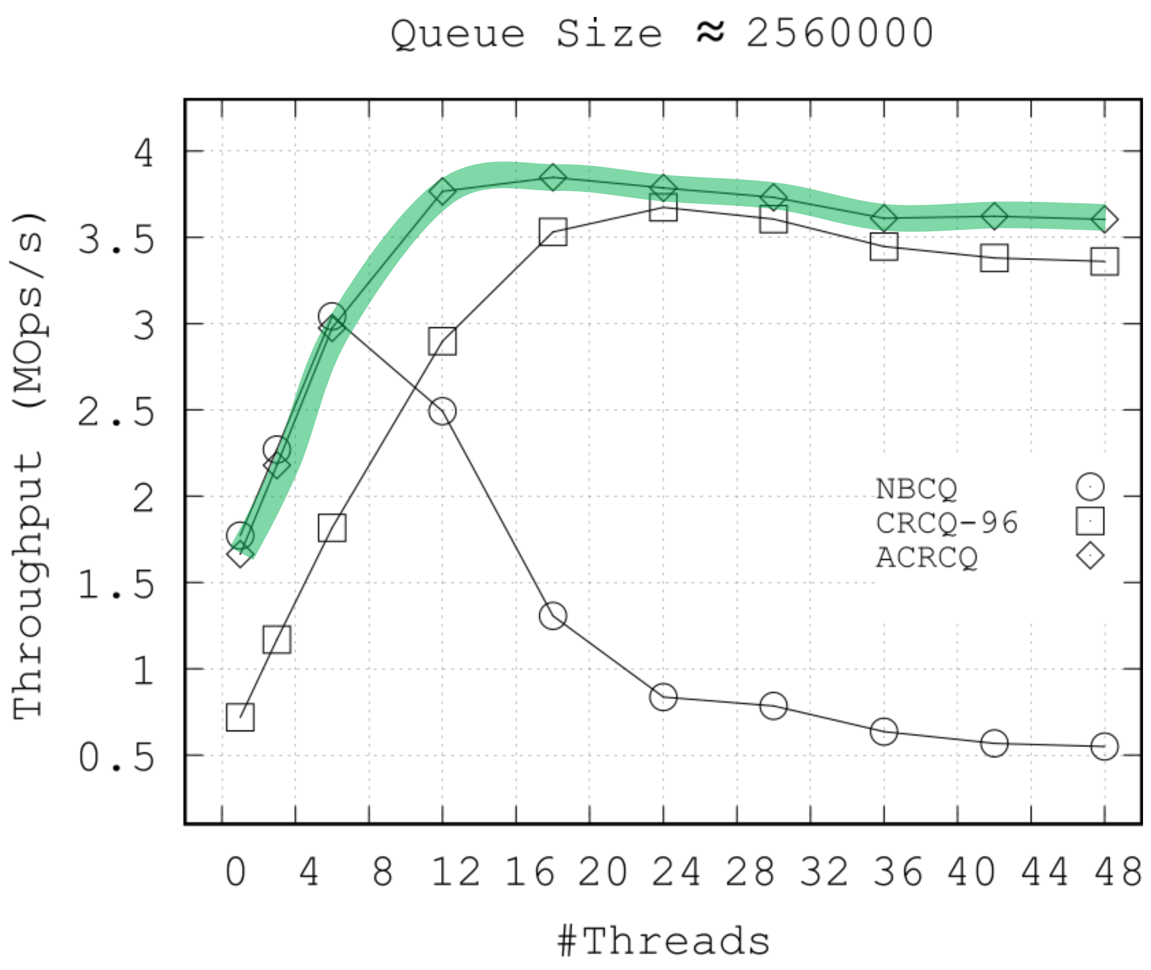
↑ THRESHOLD ⇒ ↑ READ LATENCY ☹ and ↓ RMW IMPACT ☺

↓ THRESHOLD ⇒ ↓ READ LATENCY ☺ and ↑ RMW IMPACT ☹

Conflict resiliency trade offs



Priority queues – Attempt 3



Open challenges

How to achieve scalability for priority queues?

- NO ANSWER for correct priority queue
- The research moved on looking for RELAXED SEMANTICS for priority queues
  - Enable scalability for extractions by removing an item which is “near” the minimum
- Explore orthogonal approaches by guaranteeing RELAXED CORRECTNESS CONDITIONS
  - K-linearizability
  - Quasi-linearizabilty
  - Quiescent consistency
  - Sequential consistency?
- Explore new hardware capabilities (e.g. HTM)

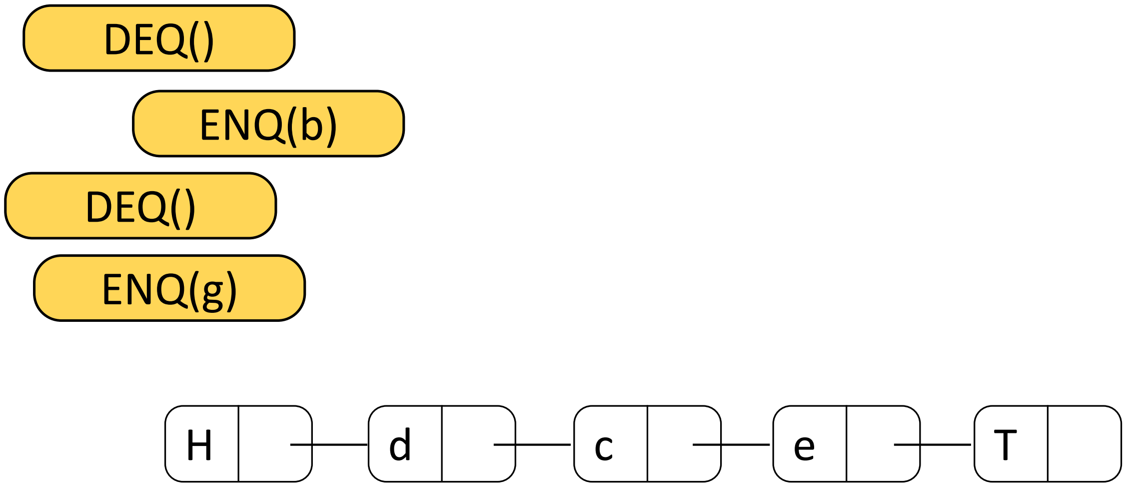
Why linearizable non-blocking algorithms?

- Performance is a good reason, but not the unique one
- The composition of linearizable algorithm is still linearizable
- Blocking algorithms (and their composition) might suffer from deadlocks, priority inversions and convoying
- The composition of non-blocking algorithms is non-blocking as a whole (progress property of individual algorithm might be hampered)
- Libraries should implement their algorithms in a non-blocking linearizable fashion
  - E.g. Java implements non-blocking concurrent data structure

Concurrent Data Structures: **FIFO queues**

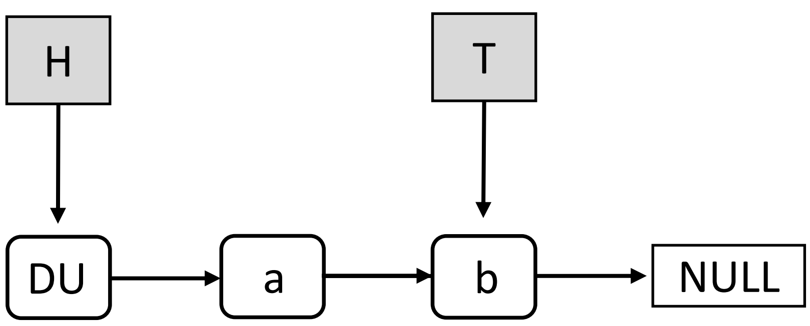
FIFO queue implementation

- Queue methods:
  - `enqueue(v)`
  - `dequeue()`
- Implemented as a linked list



FIFO queue implementation

- Slightly different
- One dummy node, two pointers to access the data structure:
  - Head: points ALWAYS to a DUMMY node item
  - Tail: SHOULD point to the youngest item



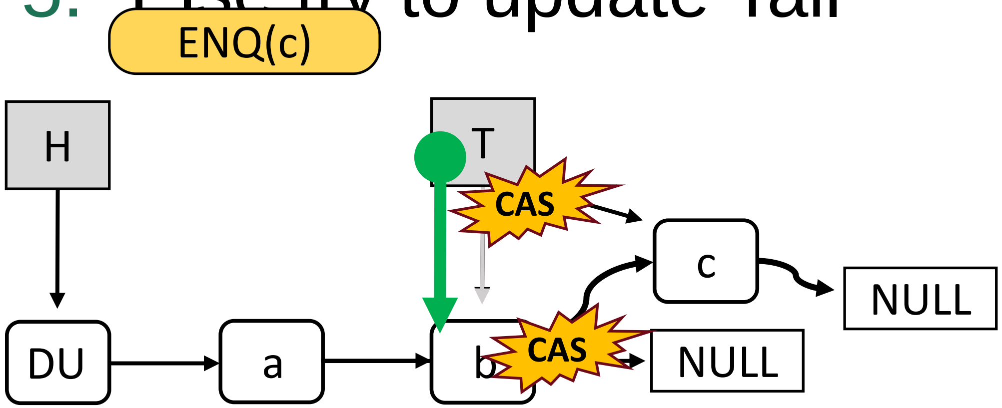
FIFO queue implementation

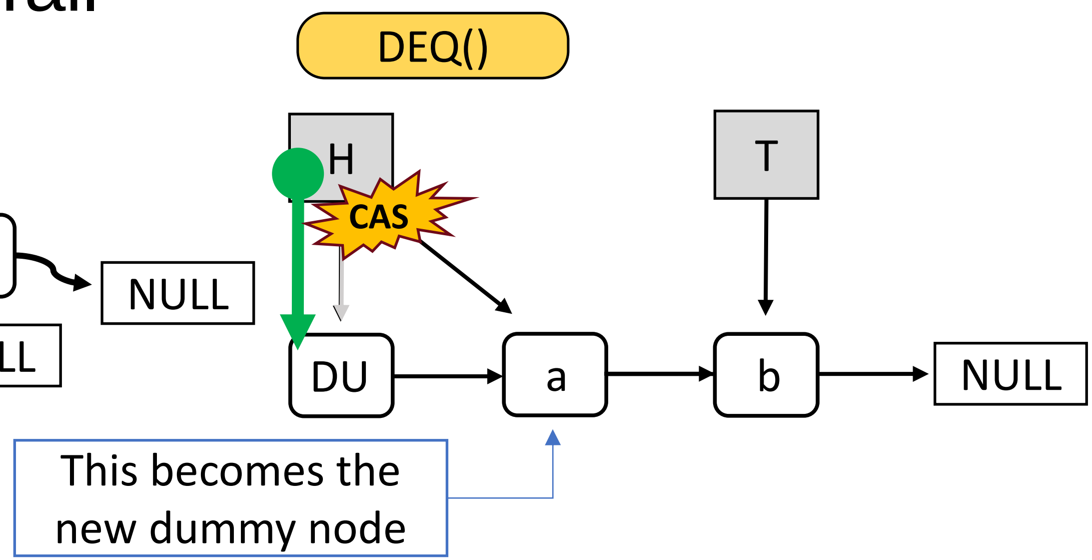
- Insert:

1. Get node pointed by tail
2. Scan until next is NULL
3. Try to insert with CAS
4. If KO goto 1
5. Else try to update Tail

- Dequeue:

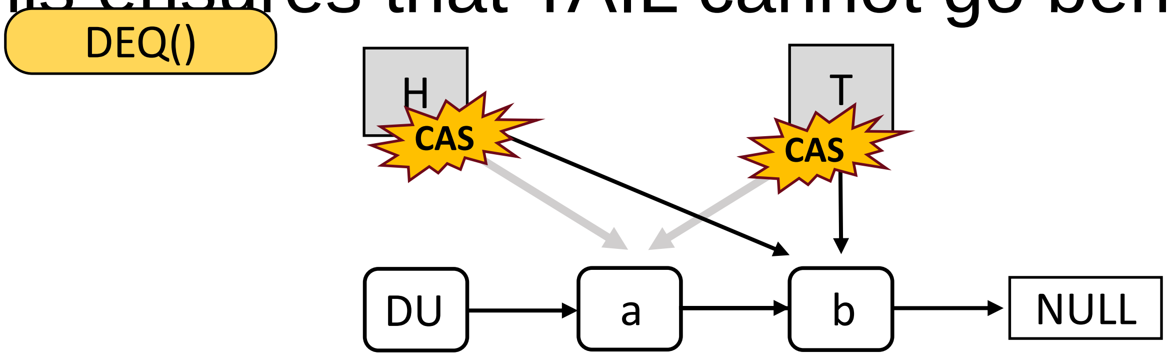
1. Get node pointed by head
2. Try to update head with its next
3. If KO goto 1





The whole story

- Since the insertion of a new item and the tail update are two separate RMW they might be inconsistent
- Also dequeuers might need to update tail before updating head
- This ensures that TAIL cannot go behind HEAD



Emptiness condition

- There is a NULL node after the one pointed by HEAD
